I. The Council, having regard to the terms of Section 18 of the Local Government Act (1888) and of Section 54 of the Local Government (Scotland) Act (1889), and observing that under these sections special privilege is to be accorded to the holders of the diplomas granted under Section 21 of the Medical Act (1886), and therein described as diplomas in sanitary science, public health, or State medicine, thinks it essential to declare, with regard to its own future action under Section 21 of the Medical Act (1886), that it will not consider diplomas to "deserve recognition in the Medical Register" unless they have been granted under such conditions of education and examination as to insure (in the judgment of the Council) the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health; and the Council, in forming its judgment on such conditions of education and examination, will expect the following rules to have been observed:—1. A period of not less than 12 months shall have elapsed between the attainment of a registrable qualification in medicine, surgery, and midwifery and the admission of the candidate to any examination or any part thereof for a diploma in sanitary science, public health, or State medicine.

2. Every candidate shall have produced evidence that after obtaining a registrable qualification he has during six months received practical instruction in a laboratory or laboratories, British or foreign, approved by the licensing body granting the diploma, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught.

3. Every candidate shall have produced evidence that after obtaining a registrable qualification he has during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Rule 2) been associated day by day in the duty, routine and special, of public health administration, under the supervision of

(*a*) In England and Wales, the medical officer of health of a county or of a single sanitary district having a population of not less than 50,000, or a medical officer of health devoting his whole time to public health work; or

(*b*) In Scotland, a medical officer of health of a county or counties, or of one or more sanitary districts having a population of not less than 30,000; or

(*c*) In Ireland, a medical superintendent officer of health of a district or districts having a population of not less than 30,000; or

(*d*) A medical officer of health who is also a teacher in the Department of Public Health of a recognised medical school.

⁂ The certificate of an assistant medical officer of health of a county or of a single sanitary district having a population of not less than 50,000 may be accepted as evidence under Rule 3, provided the medical officer of health of the county or district in question permits the assistant officer to give the necessary instruction and to issue certificates.

4. Every candidate shall have produced evidence that after obtaining a registrable qualification, he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration.

5. The examination shall have been conducted by examiners specially qualified; it shall have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory and one to practical examination in, and reporting on, subjects which fall within the special *outdoor duties of a medical officer of health.*

⁂ The rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890.

II. The Council shall from time to time appoint an inspector or inspectors of examinations in Public Health, with special instructions to report to the Council whether the examination of each licensing body does or does not afford evidence on the part of candidates passing such examination of a distinctly high proficiency, scientific and practical, in each and all of the branches of study which concern the public health.

Sir Hector Cameron, noticing some remarks by Dr. Pye-Smith relative to the application of Anglo-Indians for the diploma in public health, pointed out that the burden the committee had to consider was the burden of time. Anglo Indian applicants, he said, had usually only a year in which to come from India, obtain the diploma and return to their duties. By the resolutions and rules now submitted the time required for the diploma was compressed into nine months, the last attendances on an infectious hospital being really meant to run concurrently with the rest of the requisite education. That meant a reduction of three months in the matter of time, but certainly the burden was somewhat increased by the new rules in the matter of education.

The adoption of the rules was agreed to, and it was further resolved that a copy thereof should be transmitted to the several bodies which grant diplomas in Public Health.

Education Committee's Reports.

On the motion of Sir John Batty Tuke, seconded by Dr. MacAlister, three reports by the Education Committee were received and entered on the minutes. These reports were on: (1) the steps taken for raising the standard of preliminary examination; (2) an application from an American university for the recognition of its arts examinations; and (3) the "Medical and Pharmacy Act Amendment Act, 1899," of the Cape of Good Hope.

The report on the steps taken for raising the standard of preliminary examination was as follows. The Education Committee, at the last meeting of the Council, was "authorised to take all needful steps to give effect to the recommendations and suggestions for the improvement of preliminary examinations" contained in the joint report of their expert advisers, and to report from time to time to the Council thereupon.

The committee, in pursuance of this instruction, have communicated the joint report to all the educational bodies which hold recognised preliminary examinations within the United Kingdom, and have invited them to inform the committee as to the steps they propose to take for the improvement, when necessary, of their examinations. From a large number of the bodies they have received answers which indicate that they are *anxious to coöperate with the Council in raising* the standard of preliminary education among medical students and that they are prepared to do what is necessary towards meeting the recommendations submitted to them.

The committee have forwarded the answers and the proposed changes in examinations therein proposed to Professor McCormick for his opinion and advice and they have pleasure in communicating to the Council the following passages from the interim report to the Chairman thereupon:—

To Sir John Batty Tuke, M.P. St. Andrews, Nov. 20th, 1900.

Dear Sir,—I beg to inclose communications received as to the report of the Education Committee adopted at the last meeting of the General Medical Council. In the terms of that report (p. 31) the various bodies holding examinations at present recognised by the General Medical Council were requested to state how far in their opinion their respective examinations met the requirements of the proposals contained in that report and how far it would be desirable or possible for them to make modifications in their examinations to that end. This request has already been complied with by the following bodies:—

1. Oxford and Cambridge Schools Examination Board.
2. Oxford Local Examination Delegacy.
3. Cambridge Local Examination Syndicate.
4. Senate of the University of Birmingham.

5. Scotch Education Department.
6. Senate of the University of Aberdeen (Local Examination Board).
7. Educational Institute of Scotland.

These communications contain certain questions of detail demanding the consideration of your committee; and I subjoin remarks as to these minor points, which might be embodied in answers to the several authorities, if they meet with your approval.

Many of the bodies from whom no communication has yet been received have been unable to hold a meeting since the report was issued, but I have little doubt that before the Spring Session communications from all the bodies concerned will be received.

Meanwhile, those already received may be regarded as giving promise of a successful issue to your committee's proposals of reform.

The three first-mentioned bodies (of Oxford and Cambridge) report upon their respective examinations in full detail under the five heads laid down in your committee's report, and also indicate their willingness to make such an arrangement as will raise the qualifications of medical preliminary candidates on the lines of the committee's recommendations.

The Senate of the University of Birmingham, in reporting upon its preliminary examinations, "begs to assure the General Medical Council of its sympathy on educational grounds with the general trend of the recommendations contained in the report, and its desire to see them carried out in practice."

Sir Henry Craik, in acknowledging for their lordships of the Scotch Education Department the proposals of the Education Committee, which are met generally by the lower grade leaving certificate in its present form, adds that, "should circumstances in the future render any modification of that form desirable, their lordships will not fail to keep the wishes of the General Medical Council carefully in view."

These and similar expressions of opinion which have been received informally from representatives of other bodies show that the proposals of the Education Committee are meeting with general approval among the educational authorities of the United Kingdom and that the committee will have their cordial help in promoting the desired reforms.

I may also add that I was present at a conference of the Education Committee with representatives of the College of Preceptors, at which proposals were put forward and discussed as to the lines on which that body might best meet the committee's recommendations.

I remain, yours truly,
W. S. MCCORMICK.

Communications from certain other bodies, including the College of Preceptors, have since the date of the above been received by the committee and are at present under consideration. A certain number of the recognised examinations held for other than medical purposes which the bodies concerned are not prepared to alter will with their full assent be omitted from the list of recognised examinations which the committee have in preparation.

The report in respect to the application from an American university for the recognition of its arts examinations was as follows:—

The committee have carefully considered the application of another American university for the recognition of its arts examinations. They have resolved that they are not at present prepared to recommend the Council to place these examinations on their list.

The report on the "Medical and Pharmacy Act Amendment Act, 1899, of the Cape of Good Hope," shows that the Act of the Legislature of the Cape of Good Hope, courteously forwarded by the Secretary of State for the Colonies, has been referred to the committee by the Executive Committee. They are of opinion that the Act contains many salutary provisions, of which not a few might with advantage be extended to other portions of the empire.

Medical Aid Associations.

Dr. GLOVER submitted a report by the Medical Aid Associations Committee which was as follows:—

In making an interim report your committee have to announce that they continue to receive from various parts of the country painful proof of a certain amount of friction between the profession and medical aid associations, especially such associations as are conducted on commercial principles, with the aid of canvassing, advertisements, &c. The loyalty of the great mass of the profession to the regulations of the Council with regard to such practices should be fully realised by the Council; the more so as in several towns it has entailed at least temporary loss on some practitioners who have resigned appointments rather than expose themselves to the charge of violating the wishes of the Council. One such case has been formally brought to the notice of the Council, in the form of a complaint against a practitioner who, it is alleged, accepted office where such practices are allowed. The case, unfortunately, was brought forward too late for consideration at the present meeting. The committee continue to believe that in regard to those medical aid associations, composed for the most part of the great friendly societies, the most promising method for removing differences is in the creation of a conciliation board. The Medical Council has done all in its power to recommend and promote the creation of such a board.

The success of such efforts must rest now with the profession itself, acting through its voluntary associations, and especially the British Medical Association, the Council of which a few months ago appointed a committee to treat directly with the friendly societies on this subject. Its resolution is in the following terms:—

"The Council appoints a committee to confer with the representatives of the friendly societies with a view to drawing up a scheme for the formation of regulations regarding the powers and duties of the proposed conciliation board."

The President of the British Medical Association is the president of this committee. We are kindly informed by him that the committee has met once and decided on some matters of principle. It is to be hoped that before the meeting of the General Medical Council in May your committee will be able to give a final report on this important subject.

At the instance of Mr. HORSLEY the phrase "a certain amount of friction" (which occurs near the beginning of the report) was altered to "a serious amount of friction."

The report as amended was received and entered on the minutes.

Mr. BROWN thought that the Council ought to make very clear to practitioners connected with medical aid associations their position as regards unprofessional conduct. There was ambiguity about all the past resolutions on the subject, and because of that there were districts of the country in which medical officers of such associations who were on the Medical Register had resigned good appointments and others in the same districts who remained in their appointments, apparently because they did not know exactly what the Council wanted the profession to do. Unless the Council made their position perfectly clear they would have practitioners coming to their Registrar saying that they did not understand what the Council meant. He had framed a motion whose terms he did think clear and at the same time not too strong, and it was this:—

> That notices be published by advertisement and otherwise to the effect that association with medical aid societies and clubs, which systematically canvass for patients may be regarded by the Council as infamous conduct in a professional respect, rendering any practitioner proved to be guilty thereof liable to have his name removed from the Medical Register.

He believed that if the Council passed this proposal they would be expressing the feelings of every man in the profession who was worthy of having his name retained on the Medical Register.

Dr. BRUCE seconded.

In the course of some conversation it was suggested by Dr. MACALISTER that the Council could not judiciously consider the proposal because it would affect a penal case now pending, and in the circumstances it would be indecent on the part of the Council to pass any such motion.

Mr. BROWN withdrew the proposal in the meantime.

Financial Condition of the Council.

The next business was the receipt of a report from the Special Finance Committee, re-appointed on May 31st, 1900, to consider and report on (1) the financial position of the Council and its branches as regards assets and liabilities; (2) the relations of the income and expenditure of the Council and its branches for the last 10 years; and (3) the measures that appear to be desirable to place the Council's finances on a satisfactory basis. The report was submitted by Mr. BRYANT and the following are extracts from it:—

The assets of the General Council, the Branch Councils, and the Dental Fund consist of the following:—

(1) The freehold property vested in the Council, which consists of the Council's building, the contiguous house in Hanover-square, and the site on which they stand; (2) consolidated stock, to the credit of the English and Scottish Branch Councils and the Dental Fund, which amounts to £23,773; and (3) cash in bank, £2696.

The English branch holds, as a security for a loan to the General Council, a mortgage on the freehold property for £25,007. This will be paid back to the branch in 1949 by the Alliance Company through the operation of the sinking fund hereafter mentioned.

The General Council and the branches have no outstanding liabilities other than those regularly incurred and met during each year in carrying out their statutory duties.

The freehold property of the Council is of a highly valuable character and is sure to become still more valuable as time goes on. At present a portion of the property—namely, the house in Hanover-square—produces a yearly rent of £241 13s. 4d. When the existing lease expires, at the end of five years, there is no doubt that a considerably larger rent will be obtained.

The annual charges involved are: (1) a sum of £720 payable as interest at 3 per cent. to the English Branch; and (2) a sum of £216 payable to the sinking fund, by means of which the mortgage on the property will be paid off in 1949.

Of this annual outlay of £935 the increased rent soon to be obtained will provide a considerable proportion. The General Council may therefore look forward in a few years to holding its handsome property at a comparatively small annual charge.

The English and Scottish Branches and the Dental Fund possess the following funds in consols—viz., English Branch, £10,573; Scottish Branch, £5260; Dental Fund, £7940—which are sufficient to enable them to meet any liabilities they are likely to incur. The capital of the Irish Branch at the close of 1899 amounted to only £62, which in all probability will shortly be exhausted.

With regard to the second clause of the resolution—"(2) The relations of the income and expenditure of the Council and its branches for the last ten years"—the income of the General Council consists (a) of the rent of the house in Hanover-square, mentioned above; (b) of the proceeds of the sale of Registers, which do not nearly cover the cost of printing; (c) of the fees for registering colonial and foreign qualifications, which amount to about £40 a year; and (d) of the proceeds of the sale of the Pharmacopœia and the Addendum, 1900, which in future will be entered in a separate account. Its income, therefore, apart from the contributions of branches, is small in relation to its expenditure.

It will be convenient if each branch is considered separately, and if the expenditure is also considered under the two heads of (I.) contribution to General Council, (II.) expenses of administration of branch office.

As to the English Branch. The income is practically stationary, the average being £4,667.

Expenditure.—(I.) The requisitions of the General Council have increased; the average of the first three years of the decade is £2900, while the average for the whole period is £3800, and the contribution in 1897 reached £5000. This was due to expenses in connexion with the

Pharmacopœia, 1898, the late Registrar's retiring honorarium, heavy law expenses, and interest on the increased mortgage. These are matters over which the branch has no direct control and the question of the expenses of the General Council will be discussed under Clause (3) of the reference to the committee.

(ii.) The expenses of the administration of the English Branch average £889, being 19·06 per cent. of the income, and the cost of administration per head of registered practitioners belonging to the branch is 10·35*d*. This is somewhat higher than the proportional cost of administration in Scotland, but is accounted for by the fact, first, that an election of Direct Representatives costs over £400 in England as against about £50 in Scotland, and, secondly, that a by-election (in 1897) is included; while the branch contributed one-third of the retiring honorarium to the late Registrar, in addition to what it contributed *pro rata* to the expenses of the General Council, in which the remaining two-thirds of the honorarium were included. The following table shows how these items affect the results:—

Total expenses for the 10 years			£8399 16 3
Less election expenses, 1891 ...	£489		
" " 1896 ...	404		
" " 1897 ...	426		
One-third of honorarium	330		
			1649 0 0
			£7250 16 3

Corrected percentage of expenses to income, 15·5.

As to the Scottish Branch. The income here, too, is almost stationary, the average being £2647.

Expenditure.—(i.) Here again the demands of the General Council are the chief item. Under this head the average contribution for the first three years of the decade is £1700, and for the whole period it is £2200.

(ii.) The expenses are moderate: the average is £380, being 13·63 per cent. of the income, which is 1·87 less than that of the English Branch, taking the latter at its corrected rate.

As to the Irish Branch. The income, the average of which is £820, has diminished by the interest which used to be received on consols, this asset having now been realised to meet current expenses; but apart from this there does not appear to be any serious diminution in the annual amount of fees received; indeed, 1899 showed a distinct advance over the two previous years, and this is being maintained during the present year.

Expenditure.—(i.) With an income of £820, of which the General Council requires 81·78 per cent., the residue in the hands of the branch does not suffice to meet its necessary expenses.

(ii.) The percentage of expenses to income (40·85) is higher than in the other two branches, but it must be remembered that there are certain expenses which cannot be cut down below a certain minimum, e.g., salaries and office rent. It is necessary to have an office and also to pay a salary to the registrar and clerk, so that it cannot be said that there has been an excessive expenditure in this branch. The fact, however, remains that the branch can only carry on its statutory duties this year by the aid of the special grant of £500 made to it by the Council. This will have to come as part of the Council's expenditure, out of the funds of all the branches, including the Irish Branch, so that the net gain to the Irish Branch will be only about £100 (since the General Council requires about 80 per cent. of the gross receipts of each branch). This is doubtless a very cumbersome procedure, but in view of the provisions of Section XIII. of the Medical Act, 1858, it is the only course which the statute allows.

In considering Clause (3) of the original resolution—

"(3) The measures that appear to be desirable to place the Council's finances on a satisfactory basis"—

it will be best to take the accounts of the General and Branch Councils as a whole as they appear on pp. 10–11 of App. I., Minutes of the Council, Vol. XXXVII.

A reference to the finance reports from 1890 to 1899 shows that during the last ten years the aggregate expenditure of the General and Branch Councils has exceeded the income, including the receipts from the Pharmacopœia, on the average by about £110 a year. The difference between this amount and that of £88 6*s.* 2*d.* on the first table is due to the fact that the first yearly payment to the sinking fund (£216 12*s.* 6*d.*) was not included, as it should have been, in the year's expenses of the General Council, and accordingly the branches were not called upon to pay their proportionate share of it. Had the Pharmacopœia accounts been eliminated, as will in future be done, the excess of expenditure over income would have averaged £232 a year. It is, however, right to say that the ratio of expenditure to income has increased during the latter part of the decade.

It must not be forgotten that a new cycle of inspection of examinations is about to commence and that next year there will be elections of Direct Representatives in England, Scotland, and Ireland, the aggregate cost of which in 1896 was £488.

With regard to the receipts, it will be seen that the great bulk of the income is derived from original registration fees, the other items being of much smaller importance.

The largest item of expenditure is the cost of the sessions of the General Council, which during the last five years has averaged £3317 4*s.* 4*d.*, while the length of each session during that period has averaged seven and three-quarter days.

Since the passing of the Medical Act, 1858, in which a fee not exceeding £5 was prescribed as the registration fee, Parliament has added eight members to the Council—five members elected by the profession in the three divisions of the United Kingdom (in accordance with the provisions of the Medical Act, 1886), one each for two new universities—viz., the Victoria University and the University of Birmingham in its special Act passed this year—and two additional members for the Scottish Universities, which have now each a representative. On the other hand, the Crown is represented by five members instead of six and the President is now elected from the members of the Council. The net addition to the number of the Council is therefore seven members.

The addition of these members has necessarily imposed on the Council additional charges since the maximum registration fee was fixed by Parliament.

Of late years the amount of legal business has greatly increased and the sum of £667 has been spent since January, 1897, in connexion with prosecutions and cases before the courts alone. Also, reports of committees continue to increase in number and the conduct and record of their proceedings have of late greatly added to the cost of the item of printing.

The analysis of the accounts of the Council now presented by the committee does not appear to furnish ground for any serious anxiety as to the financial position at the present time.

It must, however, be remembered that year by year the duties which the Council is called upon to perform increase and that in consequence a longer time is required for the transaction of its business than was usually sufficient a few years ago.

The addition to the number of its members already referred to also increases its expenses during its session, the increase for each week of the sitting amounting to about £337, or at least £674 for a year containing two sessions of a week each.

The committee would therefore suggest to the Council that in order to diminish, if possible, these sessional expenses the sittings of the Council should open on the Monday instead of on the Tuesday as at present, and that the consideration of penal business should commence on Tuesday instead of on Thursday. The Executive Committee would then meet on the previous Saturday. Time would also be gained were the Council to commence its business at 1 P.M. on each day of the session.

Unnecessary expense would also be avoided were it arranged that a Direct Representative elected at a by-election should vacate his seat at a general election, so as to prevent the possibility of having an election in three years out of five, as might easily be the case in England.

Recommendations.—The committee suggest that the following be submitted to the Council for its decision:—That the Executive Committee be authorised to amend the Standing Orders as follows: (i.) that the sessions of the General Council commence on the Monday; (ii.) that a meeting of the Executive Committee be held on the Saturday immediately preceding; (iii.) that the sittings of the Council commence each day at 1 P.M.

Mr. BRYANT, in submitting this report and in moving that it be received and entered on the minutes, said that he did not think that the Council would expect him to go into details about it. One of the most striking facts it showed was that the Medical Council were not in so desperate a condition as some persons imagined that they were. The Council certainly spent a little more than their income, but, after all, the sum so expended was a small one. Last year the balance on the wrong side was only £88 6*s.* 2*d.*, but when the bank account was looked at it was seen that there were so many thousand pounds to the Council's credit that it would take many years to eat up the sum if the excess of expenditure did not exceed £88 a year. Consequently, a slight sacrifice in the way of extra expenditure could be made, even in present circumstances, without detriment to the soundness of the Council's finances. He did not need to go into the question of the Irish Branch Council's position. The Finance Committee and the General Council had found a means of letting the Irish Branch go on on a basis that would not be described as unsatisfactory to the profession. The sum at which their freehold property was valued was not at all a bad sum, and they were paying off the debt in such a way that in the year 1949 the Council would not only have at its credit property amounting in value to over £25,000, but would be the better annually of the £1000 which they had now to pay for interest and instalments for the buildings which the General Council occupied and possessed. These buildings included a house in Hanover square, and not long ago they had had a very handsome offer for it, which included the exclusion of a 20-feet strip of ground on which the Council's present premises in Oxford street could be extended. He did not say that an equal offer would at any time in the future be made to them, but if ever the house were sold the Council would get a nice round sum for the property. Having directed particular attention to the paragraph in the report which shows that the funds have to bear the expense of seven members of Council additional to the number provided for in the Act of 1858, he asked the Council to adopt the committee's recommendations appended to their report.

Sir DYCE DUCKWORTH seconded, and the report was then received and entered on the minutes.

Mr. HORSLEY moved that the Special Committee be re-appointed, that the report be remitted back to them, and that they be instructed to further consider and report upon the several heads of the resolution submitted to them in May of last year. He urged that the committee presenting the report which was now before the Council had not fulfilled the duties entrusted to them. Their report under the first two heads was gravely misleading, and he submitted that they had made no recommendation whatever under the third reference. The report was optimistic in its character, but its recommendations consisted of only three small domestic economies. It was said that there was money in the bank. He protested against the assumption that the General Council were justified in embarking on over-expenditure simply because there was money in the bank.

As a matter of fact the General Council had no money in the bank. The branches had money there, but the General Council were nearly as poor as the Irish Branch Council. Practically, they were bankrupt. The branches had a certain amount of property in their hands which they had no right to hold. Members of the Council considered that satisfactory. He did not. The General Council as a council had no funds of its own. Their treasurers had the idea that because some of the branches had money the General Council were justified in spending to the last penny. That was not the rule in ordinary life. He held now, as he had held in previous sessions, that the only satisfactory way of dealing with the finance of the General Medical Council was to obtain an amendment of the Medical Act. With reference to the last paragraph of the report he wished to say that he was the unfortunate individual that was selected at a bye-election. In respect to that he would invite the members of the Special Finance Committee to refer to his address to the electors, for in that he set it forth to the profession that "they would be taxed in this particular way," but that he intended to resign his seat when his colleagues resigned their seats. This paragraph was the most humorous part of the committee's report.

The PRESIDENT said that one reason why the paragraph referred to was inserted in the report was on account of the very example Mr. Horsley had told them to take and they had taken it not as an example to Mr. Horsley but to others. Therefore the committee had given Mr. Horsley the credit.

Mr. HORSLEY: But my name does not come in. I do not see where the credit comes in. The reference to him in this report, he went on to say, was really a ridiculous one, and it seemed absurd that a committee of this importance should put it into their report. However, what he asserted was that the only satisfactory method of putting the General Medical Council's finances on a proper basis was to provide that all funds should be put into a central office, that all the expenses of the branch offices should be managed on ordinary financial lines, and that that could only be effected by securing an amendment of the Medical Act.

Mr. TOMES seconded the motion. He did not think that members realised the fact that their average deficit for the last three years was £1800 a year. He was desirous of remitting this report back to the committee because there was no time to thrash it out this session and because he did not think that the question had been fully met. He was quite prepared to say that it was nobody's fault and that because their accounts were a sham it was owing to the Act of Parliament; but he must contend that the relations of the Branch Councils to the General Council brought out the most ridiculous results.

Sir WILLIAM THOMSON moved the closure.

Dr. BRUCE thought the matter might stand over till next session.

Sir CHRISTOPHER NIXON intimated that he wanted to speak on the report now.

Dr. MACALISTER said that the report had been misconstrued.

The PRESIDENT declined to accept the motion for the closure, at the same time expressing an opinion that further consideration of the report might very properly be held over till next session.

Sir CHRISTOPHER NIXON, who was allowed to proceed, stated to the Council that their legal adviser had shown that the Council were in an illegal position as regards their finances and that they had been advised to get an amendment of the Medical Acts in order to get out of it. It was right that the Council should endeavour to get out of it by an amendment of the Acts, and in his view the only plan that would be satisfactory would be to give all the assets to the General Council and let that Council meet the expenses of the branch councils.

Considerable impatience was shown by the comparatively few members (13 out of 31) who still remained in the Council Chamber at any desire to prolong the sitting or the debate, but the PRESIDENT pointed out that it would not be well if after the opposition speeches the Special Committee had no opportunity to reply, and when another member rose to speak he called upon the chairman of the Business Committee.

Dr. MACALISTER thereupon said that it was impossible to discuss the matter at great length but he wished to say something in reply to what had been said. As a member of the Special Committee he must say that when he entered on the investigation he knew nothing about the Council's accounts and he had taken a much more serious view of his responsibility than Mr. Horsley or Sir Christopher Nixon appeared to think. He thought the question was whether the Council were in a sound financial condition and he had addressed himself to that rather than to mere matters of detail which did not seem to be of the slightest use if any proper elucidation of the question was to be obtained. Mr. Horsley had confused two things—accounts and finance. The report presented showed that the finances of the General Council and its branches were in a position which did not call for any anxiety whatever. The accounts, owing to the serious defects of the Act, were no doubt complicated, but to anyone of ordinary intelligence they were not at all difficult to understand. He had mastered the principle of them in from 15 to 30 minutes. With regard to the alleged illegality of the Council's position Sir Christopher Nixon had absolutely misread the Council's legal adviser's opinion. The very fact that the Council were advised to apply for a new Act showed that they were doing what the law asked from them. If they had been doing anything illegal their legal adviser would have said "stop." They were hampered and tied by an Act of Parliament and they must stick to it. That was not wrong. Was it more important to ascertain whether there was plenty of money to let the Council do their work or simplify the accounts? The investigation which had been made showed that if the Council analysed the finances it would be found that they were sound and that with the very small economies recommended they could meet the expenditure by the income except to a very small extent. If there was a good ground for bringing in a new Act, that might afford a good ground for a clause to amend the Council's financial machinery, but there was no justification for getting an Act to simplify the accounts. If the recommendations of the committee were adopted there would be a saving in expenditure of from £300 to £400 per year, and then there would be plenty of money forthcoming to carry on the Council's work. The Council, it was true, had very little income at present, but for whatever it wanted it could apply to the Branch Councils and get it, so that if in one year there was a certain "excess of expenditure" in its accounts, in the following year there would be an "excess of income," and so things were balanced. As a member of the committee he had to say that it was impossible to do more than had been done, and if Mr. Horsley's proposal were adopted he for one would have nothing more to do with the inquiry.

Dr. PETTIGREW, seconded by Dr. MCVAIL, moved the adjournment of the discussion till next session.

Sir DYCE DUCKWORTH said that the committee had done their best and he also declined to proceed further with the inquiry.

Mr. BRYANT concurred. To his mind it would be useless to send the report back.

The PRESIDENT pointed out that what the committee had brought before the Council was that it had in its own power an opportunity of diminishing its expenditure by adopting the recommendations which the committee had made, but the Council did not have it within its power to pass an Act of Parliament, and that was the most difficult thing they could attempt to secure. His experience was that it was practically impossible to pass any Act of Parliament on a medical subject through the Houses of Parliament; there was no subject the Governments fought more shy of than a medical one. What the Council had to consider now was whether it was not worth their while to adopt the recommendations of the committee with which the report concluded.

Dr. MCVAIL objected to adopt such recommendations and wanted the discussion adjourned. The recommendations meant much more than finance. They contemplated, for one thing, a change in their existing times and hours of meeting which would be most inconvenient if given effect to. The present arrangement was trying enough. Four-hour sittings after committees were quite sufficient when every member had to be in his place continuously. Parliament might have longer hours, with its library, reading-room, smoking-rooms, and lobbies, and an almost complete disregard of attendance in the House itself, but it was different in the Medical Council, where a member taking his seat for the day had to remain in it practically without interruption for four hours.

Mr. HORSLEY also desired to support the adjournment.

because he wished an opportunity to expose the unconscious misrepresentations of Dr. MacAlister.

After some further discussion Dr. Pettigrew's motion was unanimously carried (at the time it was put only 13 members remained), and the treasurers (who accepted the responsibility) were asked to secure before next session an investigation of the Council's finances and accounts with special reference to the matters included in the reference to the Special Finance Committee.

Length of Sitting.

A proposal that the Council should sit six hours a day instead of the present four, which had been given notice of by Sir John Batty Tuke, was dropped.

Sir DYCE DUCKWORTH said that the Council had sat six hours extra this session. That meant an additional day and a half added to the eight days' of regular four-hours' sittings and he hoped the fact would be recognised. He considered it exceedingly bad and exceedingly unwholesome in their present chamber to go beyond the regular hours, as he did not think any good work was done and that the work done in regular hours was best.

Midwives Bill.

On the motion of Dr. MACALISTER the following report from the Midwives Bill Committee was received and entered on the minutes, and the recommendation contained in it was adopted.

The committee has considered the following letter—remitted to the committee by the Executive Committee—received from the Coroners' Society of England and Wales, bearing on the proposed legislation for midwives :—

> 20, Lupus-street, London, S.W., June 15th, 1900.
>
> SIR,—I beg to inform you that at the last annual general meeting of this society (which numbers 263 members), held on the 31st ultimo, a discussion arose upon the Midwives Bill, and eventually the following resolution was unanimously passed, namely :—
>
> "That this society, although approving of the principle of the licensing of midwives, is of opinion that the Bill now before Parliament does not provide for the adequate control and supervision of midwives." I am, Sirs, yours faithfully,
>
> A. BRAXTON HICKS,
> Honorary Secretary, &c.
>
> The Registrar,
> General Medical Council.

It was resolved to report this letter to the Council and to recommend that it be sent to the Lord President of the Privy Council with a request that it be taken into consideration by him.

The Medical Register.

The following notice of motion by Mr. BROWN was on the programme of business :—

> That a supplementary Register be published as soon as possible after June 30th in each year, giving a list of names of persons removed from the Register since the preceding Jan. 1st, through death or otherwise, and also a list of names of persons added to the Register during the same period.

When this notice of motion was reached there was barely a quorum of members present, and on Mr. Brown's saying that he would proceed with it if it were allowed to pass without opposition some derisive sounds by which he was assailed had the effect of causing the postponement of the proposal meantime.

Exceptional Cases of Registration.

The Council proceeded to the

> Consideration of an application for registration of Mr. Leonard George Boor, Lic. Soc. Apoth Lond. 1851, Mem. R. Coll. Surg. Eng. 1852, a medical practitioner entitled to be registered under the Medical Act, 1858, but who neglected to effect such registration until after the coming into the operation of the Medical Act, 1886. This application, it was stated, was duly considered by the English Branch Council on Nov. 20th, when the following resolution was passed: "That the General Council be recommended by the Branch Council to direct the registration of Mr. Leonard George Boor."

On the motion of Sir DYCE DUCKWORTH, seconded by Dr. MACALISTER, the Council agreed to the recommendation of the Branch Council.

Sir DYCE DUCKWORTH submitted the usual report from the Examination Committee in respect to the manner in which exceptional cases of students' registration had been dealt with. It contained, he said, no special cases to call attention to.

This report was adopted.

Vote of Thanks to the President.

With a vote of thanks to the President, moved by Dr. GLOVER and seconded by Dr. WINDLE (Birmingham), the seventieth session of the Council was then brought to a close.

Medical News.

UNIVERSITY OF LONDON.—At the M.B. examination for honours held in October the following candidates were successful :—

Medicine.—First Class : Edward Alfred Gates, St. Thomas's Hospital; Olive McDougall (gold medal), London School of Medicine and Royal Free Hospital; and Donald Johnstone McGavin (scholarship and gold medal), Mason College and Queen's and General Hospitals, Birmingham. *Second Class :* Louisa Hamilton, Royal Free Hospital; Mary Hannah Frances Ivens, London School of Medicine and Royal Free Hospital; William Henry Willcox, B.Sc., St. Mary's Hospital; and Louisa Woodcock, London School of Medicine and Royal Free Hospital. *Third Class ;* William Fielding Addey, University College; William Payne, Westminster Hospital; and Alfred Bertram Soltau, London Hospital.

Obstetric Medicine.—First Class : Mary Hannah Frances (scholarship and gold medal), London School of Medicine and Royal Free Hospital; Donald Johnstone McGavin (gold medal), Mason College and Queen's and General Hospitals, Birmingham; and Alfred Bertram Soltau, London Hospital. *Second Class :* Louisa Hamilton, Royal Free Hospital. *Third Class :* Eugene Michael Niall, St. Bartholomew's Hospital; Miles Harris-Phillips, University College and Royal Infirmary, Bristol; William Henry Willcox, B.Sc., St. Mary's Hospital; and Florence Elizabeth Willey, B.Sc., London School of Medicine and Royal Free Hospital.

Forensic Medicine.—First Class : William Henry Willcox, B.Sc. (scholarship and gold medal), St. Mary's Hospital.—*Second Class :* Margaret Bernard Dobson London School of Medicine and Royal Free Hospital.—*Third Class :* Wilfrid Henry Coltart, Mason College; William Gough, B.Sc., Yorkshire College; Mary Hannah Frances Ivens, London School of Medicine and Royal Free Hospital; John Wishart Little, St. Thomas's Hospital; and Alfred Bertram Soltau, London Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

OPENING OF THE NEW WING OF THE STOCKPORT INFIRMARY.—The new wing of the Stockport Infirmary, which was built in commemoration of the sixtieth year of the reign of Her Majesty Queen Victoria, was opened on Nov. 28th by Lord Newton and dedicated by the Lord Bishop of Chester. A large number of persons, including representatives of public bodies, were present. The Stockport Infirmary dates from the year 1792, when a dispensary for the treatment of the sick poor was started in Millgate by a Mr. Briscall, who was then a surgeon practising in the town. In 1832 the building was called the Infirmary and was rebuilt. It was enlarged in 1871, re-arranged in 1885, and finally further enlarged by the wing just opened. This includes wards, a mortuary and laundry, bathrooms, patients' day-rooms, and an operating theatre fitted up in the most modern style. The heating is done by hot water, and the lighting is electric. The total cost was about £12,000.

THE ALFRED HUGHES MEMORIAL.—On Nov. 24th a meeting of medical men was held in the Library, University College, Cardiff, to consider the exact form which a memorial to the late Professor A. W. Hughes should take. Dr. W. T. Edwards, Vice-President of the College, occupied the chair. On the proposition of Dr. Isambard Owen it was unanimously resolved that a medal should be founded and awarded annually in the medical school of the college and that a fund should be raised to endow the anatomical museum, which owes its origin to a gift of £350 from Professor Hughes. Since, in addition to the great services which he rendered to medical education in Wales, Professor Hughes lost his life in the discharge of what he considered a public duty, it was felt that not only his friends, but all patriotic countrymen, would take pleasure in assisting to establish such a suitable memorial. The coöperation and support of all patriotic Welshmen as well as of personal friends are therefore being invited, and the proceedings of a meeting of laymen held on the same day with the same object have already been mentioned in THE LANCET of Dec. 8th, (p. 1687). The committee hopes to raise a fund of from £1000 to £1500, the interest upon which will be devoted annually to the advancement of the museum, henceforth to be known as the "Alfred Hughes Anatomical Museum." Mr. J. Lynn Thomas, formerly senior surgeon to the Welsh Hospital, South Africa, Mr. D. W. Evans, honorary local secretary to the same hospital, and Mr. J. Austin Jenkins, registrar of the University College, have been appointed honorary secretaries to the Memorial committee and his worship the Mayor of Cardiff is the honorary treasurer. A sum of £400 has already been promised.

TYPHOID FEVER AT PLYMOUTH.—76 cases of typhoid fever have been notified in Plymouth up to Dec. 10th, with nine deaths. The mortality-rate amongst the patients treated at the Borough Hospital has been only 4 per cent.

VACCINATION GRANT.—Mr. Arthur G. B. Lory, L.S.A., public vaccinator of the Chudleigh District of the Newton Abbot Union, has obtained the special Government grant for successful vaccination.

UNIVERSITY OF CAMBRIDGE.—Dr. B. Anningson, Dr. W. Collingridge, Dr. J. F. W. Tatham, and Professor Sims Woodhead have been appointed examiners for the Diploma in Public Health; Professor A. Macalister and Dr. S. H. Habershon additional examiners for the Second and the Third M.B. examinations respectively. The Walsingham medals for biological (including physiological) research have been awarded to Mr. H. H. Dale (gold medal) and Mr. R. C. Punnett (bronze medal).

THE LATE DR. J. I. BEVAN.—Dr. John Iron Bevan, of Mumbles, Glamorganshire, died in London on Nov. 30th, in his fifty-second year, after having undergone a surgical operation. Dr. Bevan, who graduated at Edinburgh University in 1872, had been for many years in practice at Mumbles, where he held several public appointments, being medical officer of health of Oystermouth and district medical officer and public vaccinator for the East Division of the Gower Union. He was also surgeon to the Fourth Division of the Coast Brigade of the Royal Artillery.

THE SURGICAL AID SOCIETY.—On Dec. 10th the Lord Mayor of London presided at the annual meeting of the Surgical Aid Society which was held at the Cannon-street Hotel The report showed that the net income for the year was £17,000 and the subscriptions were £8942. The expenditure had been £14,695. A munificent bequest of £20,614 had been received under the will of the late Mr. Edward Mackeson of Hyde Park-square and the City guilds had supported the society liberally. During the year 25,219 appliances had been supplied.

FATAL ACCIDENT TO A MEDICAL MAN.—Mr. Edwin Thomas Griffiths, M.D. St. And., J.P., aged 77 years, of Washwood, near Birmingham, died from the effects of a fall on Nov. 27th. At the inquest it was stated that the unfortunate gentleman whilst crossing the road was knocked down by the shaft of a cart. From a statement made by the deceased just before he died it would seem that the driver of the vehicle (who has not been found) was not to blame, and the jury found that death was accidental, the result of a fall but that the evidence was insufficient to show how the fall was caused.

THE WEST KENT MEDICO-CHIRURGICAL SOCIETY.—Dr. Septimus Sunderland presided at a meeting of this society held at the Royal Kent Dispensary on Dec. 7th when the Purvis Oration was delivered by Dr. G. V. Poore. After the oration (an abstract of which will be found in another column of THE LANCET) a conversazione was held and the following exhibitions were given: Lantern Views of Historic Towns in Mediæval France and a demonstration of the Kromscop, by Mr. J. J. Vezey, F.R.M.S.; a demonstration of Wireless Telegraphy, by Mr. Leslie Miller; an Apparatus for the Production of Electrical Currents of High Potential and Great Frequency, and the Instruments used in applying the Currents, by Dr. Pepperdene; Pathological Specimens and Microscopic Sections of Eyes, by Mr. Ernest Clarke, F.R.C.S. Eng.; and Microscopic Slides and Drawings, illustrating Pathological Conditions of Diseases of the Skin, by Dr. Morgan Dockrell.

THE WATER-SUPPLY OF LEICESTER.—A suggestion having been made as to the possibility of diphtheria being conveyed by the Leicester water-supply the sanitary committee instructed Mr. H. G. H. Monk, the medical officer of health, to investigate the matter. A sample of water taken from a tap in the town was submitted to examination with the following result:—Physical: naked-eye appearances, *nil*; colour, *nil*; suspended matter, *nil*; deposit, *nil*; microscopic appearances, *nil*; odour, *nil*; reaction, neutral; temperature, 14° C. Bacteriological: 1. Quantitative examination of micro-organisms, 20 per cubic centimetre. This was the average on four experiments. 2. Qualitative examination of micro-organisms: (1) Several common non-pathogenic water bacteria were present; (2) no bacillus coli and no bacillus typhosus were detected; and (3) no bacillus diphtheriæ was detected. Remarks: The sample was excellent in every way. The number of bacteria present was very small, indeed, after 24 hours standing, there was no sign whatever of surface pollution and no organism of disease was detected.

NEWPORT HOSPITAL.—The total receipts of the recent bazaar given for the funds of the Newport (Mon.) Hospital amounted to £6068 and the expenses to a little over £200.

SEWAGE OF CAMELFORD.—At the Camelford (Cornwall) County Court, held on Dec. 6th, the Cornwall County Council applied for an order directing the Camelford Rural District Council to abstain from allowing the sewage of Camelford to fall into the river Camel. The judge made the order with costs

DIPHTHERIA IN GLAMORGANSHIRE.—At the meeting of the Sanitary Committee of the Glamorganshire County Council, held on Dec. 7th, the medical officer of health (Dr. W. Williams) reported that during the three months ended September last 882 cases of diphtheria had been notified in the county of Glamorgan, against 540 in the previous quarter.

WINSFORD COTTAGE HOSPITAL.—The Winsford (Devon) Cottage Hospital, which has been given by Mrs. Medley of Winsford Tower as a memorial to her late husband, is now finished. The hospital, which contains three wards, will accommodate ten patients and is intended to benefit more particularly the poor of the parishes of Harwill and Beaworthy. The entire cost of the institution has been borne by Mrs Medley who also intends permanently to endow the hospital

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, DEC. 10TH.

Treatment of Invalided Colonial Soldiers.

EARL CARRINGTON called the attention of the Government to the practice of sending home as steerage passengers in mail steamers wounded and invalided soldiers who have been brought to this country to recruit their health, and asked whether more suitable accommodation could not be provided for these men. His lordship spoke of the men being packed like herrings in a barrel, with steerage accommodation and steerage diet, when they were not in a strong state of health, and said that the amelioration of their lot had been left to private charity and to the generosity of the steamship companies.—Lord **RAGLAN**, the new Under Secretary of State for War, replied on behalf of the Government. The expression "steerage" he said, was somewhat unfortunate, for the men had a third class passage with a bunk in a cabin and a dietary that was varied and plentiful These soldiers had been brought home as invalids from South Africa in order to relieve the pressure on the base hospitals and the convalescent homes in South Africa. Wherever possible, of course, they had been sent straight to their homes in the colonies They were not really invalids; in far the greater majority of cases they had recovered their health and strength, and if they had not entirely recovered they were, at least, far advanced towards convalescence, and therefore it was no great hardship to ask them to travel third class Where a man was considered to be in a delicate state of health and needing more attention and perhaps more luxury he was provided with a second-class passage. If these men, on account of their superior social position, were all to be given a second class passage, the same reason would apply to the men of many other corps such as the Imperial Yeomanry and the City Imperial Volunteers.—Lord **MONKSWELL**, Lord **TWEEDMOUTH**, and the Earl of **ABERDEEN** expressed dissatisfaction and disappointment with the answer made on behalf of the Government Lord **ABERDEEN** thought that the medical officers should be encouraged to ascertain the true position of affairs in order that the men themselves might not appear to be over-particular.—The Marquis of **LANSDOWNE**, late Secretary of State for War, insisted that the picture had been overdrawn The accommodation given to these men was what was known as superior third class, and it was quite unfair to speak of them being packed like herrings in a barrel.—Lord **STRATHCONA** and **MOUNT ROYAL** said he had no doubt that there had been some shortcomings and he urged the Government to make further inquiry into the matter—Earl **CARRINGTON** said that he had never heard of this "superior third class" accommodation, and told the House that one man had a temperature of 104°F.; that others were in great pain from wounds, and that others again were recovering from enteric fever. He was so dissatisfied with the answer of the Government that on an early date he would move and take the sense of the House on the motion "That this House disapproves of the arrangements made by Her Majesty's Government in sending back invalided and wounded colonial soldiers."

HOUSE OF COMMONS.

FRIDAY, DEC. 7TH.

The Constituents of Beer.

Mr. **FREDERICK WILSON** asked the President of the Local Government Board whether he would take steps to define the word "beer," like bread, butter, &c., or whether beer was still to be made of any imaginable article grown, manufactured, or imported into the country.—Mr. Grant Lawson, replying for Mr. Walter Long, said: Legislation would be necessary to give effect to the wishes of the hon. Member and I am afraid that I could not undertake to introduce a Bill for the purpose. I may point out that adulteration of beer may be dealt with under the existing law.

Monday, Dec. 10th.

The Report of the South African Hospitals Commission.

Mr. Balfour, replying to a question addressed to him by Sir Walter Foster, said he was informed by the South African Hospitals Commissioners that they hope to be in a position to present their report early in the ensuing year.

Tuesday, Dec. 11th.

Medical Colleges and the Corporation Tax.

Sir John Tuke asked the Chancellor of the Exchequer whether he proposed to impose the corporation tax (1894) on the Royal Colleges of Physicians in London and Edinburgh, having regard to the fact that the two Colleges administer and regulate medical education and examination and maintain laboratories for original research, that they are consulted by Government and by municipal authorities in matters relating to public health and medical matters generally, and that each Fellow of the Colleges is required to pay a stamp duty of £25 on election as Fellow, whereas the Institution of Civil Engineers has, by a decision of the House of Lords, been exempted from payment of the corporation tax; and whether, in face of the fact that the corporation tax has never been levied, he proposed to make the Royal Colleges liable for five years of arrears, thus placing a strain on the resources of two bodies who perform the services indicated for the State.—Sir Michael Hicks-Beach replied: The question of the liability of the Royal Colleges of Physicians in London and Edinburgh to pay corporation duty was raised by the Board of Inland Revenue in 1894 and was disputed by the Colleges. It was allowed to remain in abeyance pending a decision on a similar claim made on the Royal College of Surgeons, which has since been decided in favour of the Crown by the Court of Appeal. Following this decision the Board of Inland Revenue feel compelled to press their claim on the Royal Colleges of Physicians of London and Edinburgh. The facts of the case differ from those in the case of the Institution of Civil Engineers.

Reserve Men and Medical Attendance.

Captain Norton asked the Secretary of State for War whether it had been brought to his notice that the wives of non-commissioned officers and men in the Royal Reserve in receipt of separation allowance have been refused medical attendance for themselves and their children in cases where they do not happen to live within a mile of a military medical man or civilian practitioner in attendance on troops; and whether, seeing that reserve men came forward voluntarily at a time of national danger, are only temporarily employed, and consequently cannot conveniently alter their domestic arrangements, steps would be taken to place the families of all of them upon an equal footing as regards medical attendance, irrespectively of their abode.—Mr. Powell Williams replied: The families of soldiers of the Royal Reserve are being treated on the same lines as those governing the medical attendance of the families of soldiers of the regular forces. The same privileges have been extended to them when separated from their husbands. It is not possible to provide medical attendance for those residing at a distance from military headquarters.

Typhoid Fever among the Troops in South Africa.

Mr. Powell Williams, in reply to Sir Walter Foster, said that the total number of cases of typhoid fever among the forces in South Africa from the beginning of the war to Sept. 28th, 1900, was 15,655, the number of deaths from that disease 3642, and the number sent home as invalids 9128.

The Beer Poisoning Cases.

Mr. Balfour, in reply to a question on this subject, said that he was informed by the President of the Local Government Board that his department had from the first outbreak of the epidemic had the matter under observation. One of the medical inspectors had been visiting the places affected and had been instructed to obtain all possible information on the subject, including the action that was being taken, both by those interested in implicated breweries and manufacturers of brewers' sugar and by the local authorities, for detecting arsenic in beer and other substances which contain chemically manufactured sugar. The Board were issuing circulars to local authorities recommending them to take samples, to be analysed, both of beer and articles of food in which glucose and other substitutes were used.

Medical Provision for the War in South Africa.

At this sitting of the House Mr. Brodrick, the new Secretary of State for War, introduced in Committee of Supply a supplementary vote of £16,000,000 for the conduct of military operations in South Africa and China Various aspects of the South African campaign were discussed, many references being made to the medical provision. With regard to the bringing home of sick and wounded Mr. Brodrick announced that he had given instructions that as many as possible should be returned in troopships and should not have to mix with other passengers, that they should be under the control of an officer who would attend to their comfort, that in any case of a man who was ill he should be returned second-class at a superior rate, and that there should be careful selection of ships. He had given instructions that all the sick and wounded, whether partially recovered or not, who had to be returned in mail-steamers should have a higher rate of accommodation.—Sir Walter Foster, in the course of his speech, expressed the hope that however long the war might yet last more efficient and effective steps would be taken to preserve the health and lives of the soldiers from the attacks of disease. He commented on the prevalence of typhoid fever and said that it was mainly due to the fact that proper precautions against the disease had not been taken from the beginning of the operations. He had discussed the subject with some of the eminent surgeons who had been at the front, and they all agreed that the one great thing wanted was proper sanitation in the camps. He hoped that the Secretary of State would take into his serious consideration the advantage of following the example of other great Powers and of having attached to our army some kind of sanitary corps which would prevent a repetition of the mistakes that had been made in South Africa with regard to the sanitation of the camps. Sir Walter Foster also referred to the treatment of invalids on their way home and to the insufficient strength of the Royal Army Medical Corps.—Mr. Brodrick assured Sir Walter Foster that his suggestion about a sanitary corps would be carefully considered along with other suggestions on the same subject. He hoped that it would not be supposed that he was either temporising or endeavouring to put off a decision upon this important matter, but it was absolutely impossible at this moment for him to enter into the question of what required to be done for the medical service in South Africa. It was a subject in which he in common with every Member of the House had the deepest possible interest. They had a commission sitting, and if anything that he could do would induce that commission to report at an earlier date than it would otherwise do he would only be too pleased to do it. It was impossible that the question of the medical service could be put aside, but it could not be dealt with until they had received the report of the commission. He would ask the House to have confidence that when the report was received the action of the War Office would be prompt and that no preconceived ideas of any sort or kind would interfere with their taking whatever measures might be necessary, however drastic, to put the medical service upon a proper footing. They did not wish to prejudge the matter in the least. In a campaign of this kind there must be occasions when men received less medical assistance than was desirable. A sanitary corps to inspect each camping-ground would be an ideal state of things, but he did not think it would be possible in the case of every small camp. However, their minds were open and there was nothing either in labour or in examination which would be stinted to give proper effect to the suggestions which might be adduced.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Adams, E. G. B., M.B. Lond., F.R.C.S., has been appointed Medical Officer for No 1 B. Sanitary District by the Longport Board of Guardians and Rural District Council.

Anderson, D. E, M.D. Paris, has been appointed Visiting Physician to the Hertford British Hospital, Paris.

Bates, T., L.R.C.P., L R C.S. Edin., M.R.C.S., has been re-appointed Honorary Surgeon, Worcester General Infirmary.

Bathurst, L., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Ellesmere Union, vice J. Griffiths.

Bernard, G., M.D. Canada, L.R.C P., L.R.C.S. Edin., has been appointed District Medical Officer, Sunderland Union.

Bonner, T. J., M.B., C.M. Aberd., has been appointed Medical Officer of Health, Towyn Urban Sanitary District, vice B. M. Bone, resigned.

Brand, G. H., M.D. Brux., L R C.P., L.M. Irel., L S.A. Lond., has been appointed to examine Candidates for the Royal Navy and Royal Marines for the Northampton District.

Brickwell, J., M.R.C.S., has been re-appointed Medical Officer for the Stoke Pogis Sanitary District, Eton Union.

Brown, J. Walter, B.A., M B., B.Ch. Irel., has been appointed House Surgeon to the Children's Hospital, Forest House, Nottingham.

Budd, H. G., L.R.C.P. Lond., M.R.C.S, has been re-appointed Honorary Surgeon, Worcester General Infirmary.

Byford, W. F., L.R C.P. Lond., M.R C.S., has been appointed Medical Officer of Health for the Borough of Ruthin, vice D. Jones, resigned.

Cooke, R. P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer, West Bromwich Union, vice C. Lyddon, resigned.

Drew, Douglas, B.S., M.D. Lond., F.R.C S. Eng., has been appointed Surgeon to the In-patients at the Hospital for Women, Soho-square, London.

Ellis, R. Sidney, M.B., Ch.B. Edin., has been appointed Resident Medical Officer to the St. Mary's Hospital for Sick Children, Plaistow, E.

Ensor, C. A., L.R.C.P. Lond., M.R.C.S., has been appointed District and Workhouse Medical Officer, Tisbury Union, vice J. A. Ensor, deceased.

Grace, Alfred, L S A. Lond, has been appointed Deputy Medical Officer for the No 1 District and the Workhouse of the Thornbury (Gloucestershire) Union.

Hadfield, P. Heywood, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer of Blackadon Asylum, Devonshire.

Haworth, J. T., L R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Filey District Council.

Hill, F. A., M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer, Stroud Union, vice F. E. Gordon, resigned.

Hobhouse, Edmund, M.D. Oxon., M.R.C.P., has been appointed Physician to the Alexandra Hospital for Children, Brighton.

Hudson, O. H., L.R.C.P. Irel, M.R.C.S., has been appointed Medical Officer of Health for the Dronfield Urban Sanitary District, vice H M. Richards, resigned.

Hutchens, Harold J., has been appointed Medical Officer of Health to the Joint Board for the Prevention of Epidemic Diseases, Brisbane, and to continue to act as Medical Superintendent of the Plague Hospital.

Kirk, T. D., M.D., M.Ch. Irel., has been appointed Medical Officer of Health, Montgomery Urban Sanitary District, vice T. Morgan, resigned.

Manning, Ernest J., M.R.C.S., L.R.C.P. Lond., M.B. Durh., has been appointed Junior Assistant House Surgeon to the Royal Devon and Exeter Hospital, Exeter.

MAPLETON, H B, M D Edin, D P H Lond, has been appointed Medical Officer of Health Newton Abbot Urban Sanitary District vice W Harvey, resigned

MITCHELL, C M, M D, M Ch Irel, has been appointed District Medical Officer, Oakham Union, vice G Shields, resigned

RANDALL, WYNDHAM M R C S, L R C P Edin, has been re appointed Medical Officer of Health by the Penybont Rural District Council South Wales.

ROBB J B L., M D Aberd, has been appointed District Medical Officer, Burnley Union vice S Lawson resigned

RODERICK, SYDNEY JAMES, M B C M Edin, has been re-appointed Medical Officer of Health for the Borough of Llanelly, Carmarthenshire.

SHEAHAN, GERALD L R C P & S Edin has been appointed House Surgeon to the Royal Southern Hospital Liverpool

SOUTHEY A J M R C S, has been re appointed Medical Officer for the Colnbrook Sanitary District

TRUMPER, W A, M R C S, L R C P Lond, has been appointed Assistant House Surgeon to the Royal Devon and Exeter Hospital Exeter

WARBURTON, W P, M D Edin, has been appointed Medical Officer of Health, Skirlaugh Rural Sanitary District, vice C Soloman

WESTERMAN ARTHUR, M B, Ch B Aberd, has been appointed Senior Resident Medical Officer to the North west London Hospital Kentish Town road N W

WHITEHEAD, ARTHUR E L R C S, L R C P Edin, has been appointed Assistant Resident Medical Officer to the St. Mary's Hospital for Sick Children, Plaistow, E

Vacancies.

TYNEMOUTH VICTORIA JUBILEE INFIRMARY —Resident House Surgeon Salary £100 with board, residence and attendance Apply to the Secretary, 43 Howard street, North Shields

UNIVERSITY OF EDINBURGH —Additional Examinerships in Medicine and Science

VICTORIA HOSPITAL FOR CHILDREN Queen s road, Chelsea —House Surgeon for six months Honorarium £25 with board and lodging in the hospital

WARRINGTON INFIRMARY AND DISPENSARY —Junior Resident House Surgeon Salary £100 per annum, with furnished residence and board

WESTERN GENERAL DISPENSARY, Marylebone-road London —Two Honorary Surgeons

WEST DERBY UNION —Resident Assistant Medical Officer for one year at Mill road Infirmary Everton Liverpool unmarried Salary £100 with rations Subject to statutory deduction, Apply to the Clerk to the Guardians Brougham Terrace, Liverpool

WEST KENT GENERAL HOSPITAL, Maidstone.—House Surgeon, unmarried Salary 100 guineas rising 10 per annum to 120 guineas with board and residence Also Assistant House Surgeon for six months Honorarium at the rate of £50 per annum, with board and residence

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton —Assistant House Surgeon for six months Honorarium at the rate of £75 per annum will be given Board, lodging and washing provided

Births, Marriages, and Deaths.

BIRTHS

CARRUTHERS —On Dec 9th, at Riverside, Batheaston, the wife of Alan Eskrigge Carruthers, M A., M B Cantab, of a son

COLLINS —On Dec. 1st at The Mall Wanstead, Essex, the wife of George W Collins, M R C S Eng, L R C P Lond, of a son

JAMES —On Dec. 6th at Sunnyholme, East Cowes Isle of Wight, the wife of Captain S P James I M S, M B Lond of a daughter

MUNRO —On Dec. 4th at Sweetbriar Cottage, Nantwich the wife of John Douglas Munro M D of a daughter

WEICHERT —On Dec 9th, at Rydal Mount, Penygraig Glamorgan, Constance wife of C J Weichert, M R C S, L R C P Lond, of a daughter

MARRIAGES

HILLIARD—HAZELL.—On Dec 8th at St George s, Bloomsbury, Harvey Hilliard, M R C S, L R C P Lond, of Wilton place, S W, to Charlotte Rippon younger daughter of Walter Hazell, of Russell square London

PERRY—GORDON —On the 19th Nov 1900 at Agra India, Francis Frederic Perry, F R C S, Lieutenant Colonel Indian Medical Service to Hilda Madeleine daughter of D Clunes Gordon, Esq

WARING—HILL.—On Dec. 10th at St. George s Church, Campden Hill W, Holburt J Waring M S, B Sc., F R C S, of Upper Wimpole street, W, to Annie Cassandra, daughter of the late Charles Johnston Hill of Holland park, W

DEATHS.

SMITH.—On Dec 6th at his residence, 23 Park road, Plumstead, John Smith M R C S Eng L S A. Lond, aged 69 years

TERRY —On Nov 24th 1900, at Daventry, May wife of John Terry, L R C P Lond, M R C S Eng Also on Dec. 2nd, 1900, at Reading John William, son of the above, aged 20 days

N B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

"THE MEDICAL PROVIDENT LEAGUE."

To the Editors of THE LANCET.

SIRS,—Confidently relying upon the motto which THE LANCET has so well upheld during its distinguished career, "Audi alteram partem," I would submit that there is another side to the arguments advanced in your issue of Dec. 1st (p 1629) concerning the Medical Provident League. In the first place, and with reference to your statements concerning the National Deposit Friendly Society, you note that that society "is sincerely desirous to receive the active support and confidence of the medical profession." You doubtless approve of that desire, for THE LANCET has often and conclusively demonstrated how painfully different is the attitude assumed towards the profession by other provident societies. Yet you paraphrase that desire to mean—"in other words, the National Deposit Friendly Society will be much obliged if medical men will combine together to act as canvassers for the society" May I point out that the interpretation is scarcely logical, and as the honorary consulting physician for the London division of the society I am able to say that it is totally inaccurate. The society has never expected, nor does it desire, medical men to canvass for it. The society would be glad to have an organised medical body to deal with, through which any suggestions which may be advanced, perhaps any complaints which may be needed, from its medical officers all over the country might be brought directly and officially to the governing body of the society; instead of vague opinions filtered through official after official from one district, and often flatly opposed to equally vague opinions expressed from some other town. The society, in fact, desires to work in perfect harmony with the medical men who work for it; and it is indisputable that this would be assisted by official communication between bodies representative of both parties. I venture, therefore, to submit that, instead of being adversely criticised, the society deserves the greatest credit for attempting to obviate by such friendly understanding any chance of the friction and the misunderstandings which are so rife between other provident bodies and their medical officers; for assisting, in fact, to institute a most practical conciliation scheme for its own workers—the very system which THE LANCET has so eloquently advocated, which medical authorities have approved, but which seems at present unlikely to be generally adopted.

Permit me to point out that you are in error about the insurance scheme of the society. It was sanctioned last May; it has a *clientèle*, to commence with, of 56,000 members; it is only waiting for Jan. 1st to formally commence its work. I must enter a very respectful protest against your description of local secretaries of the new League as "touts." Their duties would be to work for the objects of their professional association exactly as many now work in every district for the British Medical Association or the Medical Benevolent Fund. By parity of argument the latter gentlemen are "touts"—a description which I can quite imagine they might fairly disapprove of. Finally, you advise the National Deposit Friendly Society that "it should coöpt as acting members of its general committee representatives chosen by several hundreds of the medical practitioners" who now work for the society. That is precisely the very thing the society has offered to do. But it not unnaturally asks for a representative medical body to nominate those representatives. It will scarcely be suggested that the society should ask some 1500 practitioners to meet in a casual way, in some place of assembly, somewhere, for the sole purpose of choosing representatives on the governing body of the society; or that it would be humanly possible, without an enormous expenditure of time, trouble, and money, for candidates to be selected, and representatives finally chosen, merely by correspondence with 1500 busy men.

Will you next permit me, Sirs, to point out that this friendly society is distinguished from others by certain remarkable features. It has no contract work. It pays practitioners promptly for every attendance on its members, on a scale of fees drawn up and agreed to by, and modified from time to time at the desire of, medical practitioners. It is in no sense a commercial undertaking striving for the profit of shareholders, but a mutual benefit society for the working classes. By general acknowledgment, the society treats its medical officers with courtesy and respect. It is extending with such great rapidity amongst the working classes in this country that it is safe to predict that at no distant period it will be one of the foremost friendly societies in the United Kingdom. Of its own free will—merely to prevent friction and misunderstandings, merely in order to work with the medical profession in the future, as in the past, with harmony and mutual good feeling—the society has offered to do all in its power to welcome, and to officially recognise, an organisation of medical men willing to work for its members.

So far as the Medical Provident League—now definitely formed—is concerned, its position is equally defined. Quite independently of this friendly society, or of any other, the League proposes to devote its energies to work for reforms which none have proved more conclusively than THE LANCET are most urgently needed for the welfare of general practitioners and for the good name of the medical profession. I am, Sirs, your obedient servant,

Upper Wimpole-street, W., Dec. 4th, 1900. BEDFORD FENWICK.

To the Editors of THE LANCET.

SIRS,—I read the most extraordinary circular which appears in THE LANCET of Dec. 1st (p. 1629), referring to the above society, and think that in your strictures on it you have just hit the right nail on the head. You pick out the two weakest points—I quote your words: "Rate of remuneration for medical service and the wage limit above which medical service cannot be rendered; there are other things which might be discussed." A few years back I was called on by an agent of the above society, shown the rules, told that other medical men in the town would act for it and accept the rate of payment, and assured that this was no common club, that while working-men would be admitted it was for a class above that; the names of several prominent well to-do business men, each employing a considerable number of hands in the place, were mentioned to me as members, and I was asked would I act for it and accept the stipulated rate of payment. I declined, pointing out my reasons to some of my opponents, but failed to convince them, and the society got a footing here. Now, I am trusting to my memory, which is fairly good, but if I am wrong I will gladly admit it, and some of the rules may have been altered since then, yet, if you allow me the space—and I feel sure in the interest of the battle with the clubs, you will—I will point out the weak points of this society's rules and actions. A handbill was issued, which I sent you at the time, calling a meeting; a baronet was to take the chair, members were invited to join, and it was specially stated in this printed issue that position in life would be no bar to membership. The rules stated that for the fee of 1*s.* a member would be passed by the medical officer (and not only passed, but he had to be classified in a certain category according to his state of health at the time, all for 1*s.*); a fee of 2*s.* 6*d.* (two shillings and sixpence) would be paid for visit and medicine to last two days. I could see no provision for payment of visits at night or those required at times oftener than once in two days. I was told, when I pointed out that there was no wage-limit, that higher fees would be paid for those who join for higher sick pay, but my experience has been that very many of the better class who join this society and other clubs want the doctors cheap and do not pay to these societies at such a rate as to bring in to the medical attendant a remuneration in any proportion to his services and their own income. As an illustration, I was once asked, earlier than the establishment here of the National Provident, to allow the "honorary" members of the Rechabites to be placed on my list with the ordinary members and attend them for the club fees paid for the latter. I need not say that I declined to accept this but their names were mentioned to me and these were in most instances those of the very men whom I objected to as joining the National Provident; they were still bent on getting a cheap medical attendant—thrifty to meanness. If the National Provident and other benefit societies would only stick to the working and keep out the middle classes they would find it best for their own interests. We have now established a strong union in this and an adjacent county, taking in those medical men living on the borders of another as well, and hope to do good service in weeding out "sweating" by medical aid and other kindred institutions and level up to a higher plane contract work. Thanking you in anticipation,

I am, Sirs, yours faithfully,

Eckington, Derbyshire, Dec. 1st, 1900. WALLACE B. CROSKERY.

THE YOUNG LADIES' SCHOOL OF ARTS.

A CORRESPONDENT sends us a page cut from a little book with the above title printed presumably about the end of the last century and bearing internal evidence of being the composition of a Scots-man or -woman. The page contains recipes or prescriptions which would be considered scarcely suitable nowadays for the perusal of "sweet seventeen." One of them is headed "For Barreness," and runs as follows: "The man and the woman are to drink a teacupful of clove water before they go to bed; this is a sovereign remedy in Egypt in these cases, and Dr. Hasselquist says that he was told at Cairo that a woman who had been barren for many years had conceived by using this simple medicine. A midwife told himself that she had often prescribed it with success." Miss Pinkerton would have been horrified had such a prescription found its way inside the chaste gates of the Academy on Chiswick Mall.

"THE BATTLE OF THE CLUBS: A SUCCESSFUL PRECEDENT."

To the Editors of THE LANCET.

SIRS,—The answer to Mr. C. B. Townshend's inquiry in THE LANCET of Dec. 1st (p. 1630), is that our collector is paid a nominal salary of 1*s.* a week (which makes him legally our servant) and 10 per cent. on the collections. At first canvassing was not only permitted, but we considered that it was necessary, for otherwise the existence of our association could not have become so generally known amongst the working classes and without it we could not well combat the large medical aid society which was opposing us. Our committee did not, under the circumstances, hesitate to canvass, for it must be remembered there is a very great difference between canvassing in the interests of an individual practitioner and canvassing for an association which represents practically the whole of the medical profession in the town For some little time, however, our collector has not been allowed to canvass, partly because we did not feel that latterly anything was gained by it, but principally because we were anxious to observe the letter as well as the spirit of the resolution passed by the General Medical Council in June, 1899 And practically, though there is no absolute guarantee that the collector does not and cannot canvass, yet when it is remembered that he makes a very good income without canvassing, that canvassing is contrary to our express instructions which he can only infringe at his peril, and, lastly, that we never receive complaints from any source of canvassing having occurred, I think we are justified in concluding that Mr Townshend's apprehension that our instructions will prove "futile" is not likely to be realised One positive advantage in paying the collector by commission is that he is stimulated to collect "arrears" with regularity, which is of course, very important in the interest of both medical men and members

I am Sirs, yours faithfully,

Dec. 1st, 1900 A HARPER, Hon Sec

TREATMENT OF CONSUMPTION BY ARSENIC

To the Editors of THE LANCET

SIRS,—I should feel much obliged if you or any of your readers could kindly inform me whether anything is known in this country of Professor Gautier's treatment by the use of cacodylate of soda as described by the Paris correspondent of the *Daily Telegraph* of Dec. 1st as the result of an interview with the professor According to this Professor Gautier has been employing this remedy for some considerable time and with large, though not invariable, success I should also like to know where it is to be obtained and whether it is administered by the mouth as well as hypodermically and if so in what doses and in what form.

It appears his method of administration is to inject two centigrammes the first day and five on the second and subsequent days for a week and then to stop for a week, and so on every alternate week

I am, Sirs, yours faithfully,

Dec. 4th, 1900. L R C P & S I

*** The subject is dealt with in an annotation this week, and frequent references have been made to the subject in our columns See THE LANCET of June 17th (p. 1667) and Nov. 18th (p 1408), 1899, and March 10th (p 736), April 7th (p 1037) and Nov. 17th (p. 1446), 1900 —ED L.

A SUGGESTION FOR THE UNIVERSITIES OF OXFORD AND CAMBRIDGE

To the Editors of THE LANCET.

SIRS,—The University of Durham is open to any medical man who has reached the age of 40 years and has been over 15 years in the practice of his profession and who passes the necessary examinations What is really wanted is for the other universities in Great Britain to open their portals a little wider and to admit any registered practitioner to offer himself for the degree of Doctor in Medicine. There would be a direct inducement for post graduate study during the early years of waiting for practice, the standard of examination should not be lowered in any way and the age might remain as at present, not lower than 25 years In this way the universities would hold out the truest inducements for continued study and I do not think that they would in any way injure their residential graduates and at the same time they would replenish their empty money chests The University of Cambridge has for years past been appealing to the public for subscriptions, which appears to me to be a far more undignified position than would be the acceptance of fees from London and other diplomates for the degree of M D The University of Cambridge already confers a diploma in Public Health upon qualified medical men who have never given any residence in Cambridge, Oxford also does the same, surely they could be induced in conjunction with a little persuasion from the Royal Colleges of Physicians and Surgeons of London to swing their portals a little wider and thus take away a bone of contention from those who are so eager to call themselves "Doctor"

I am, Sirs, yours faithfully,

ONE WHO HAS PASSED THE EXAMINATIONS AND TAKEN THE DEGREE OF DOCTOR OF MEDICINE AFTER HAVING COMPLETED HIS FIRST HALF CENTURY.

Dec. 2nd, 1900

"MOTOR CARS FOR MEDICAL MEN"

To the Editors of THE LANCET

SIRS,—Permit me to give my experience of 12 months use of a motor-car Having had serious losses with horse-keeping I determined as an experiment to try a car. I sold out and bought a "Benz and started running it in October, 1899 My coachman soon dropped into its management. We have run it every day with, perhaps two or three exceptions at the most, since, and I have never had occasion to hire, although I quite reckoned upon having to do so at one time or another I have also used it in fine weather when not busy for making excursions into the country, sometimes going 40 miles in an afternoon Our only troubles have been due to our own want of knowledge and not to any fault in the engine. They consisted of a hot bearing on two occasions due to our own fault in not properly looking after the grease boxes, and of short-circuiting of the electric current, generally at a point on the top of the battery under the seat, the result of imperfect insulation. This is remedied (when discovered) by inclosing coil in an old piece of hose-pipe split down the middle and sprung upon the coil

The initial outlay on purchase of car was £230, which included hood, apron, electric light to lamps, and one inside, &c. The expenses for the 12 months have been: repairs, painting, &c (engineer and coach-builder), £12 10*s* 6*d*, petrol, £10 17*s*; carriage, &c, £1 10*s* 2*d*, pair of new chains, £3, re-charging cells five times, 7*s* 6*d*, total £28 5*s* 2*d* I can quite understand a motor-car giving trouble to an owner who has no taste for, or much knowledge of, mechanics, for it wants learning, but when thoroughly understood a great deal of expenditure for repairs, &c., is saved, and in my experience there can seldom be any difficulty I have travelled through water about two feet deep and through snow when my professional brethren were unable to take their horses out. My troubles with the car have been as nothing compared to those of a brother practitioner, who to my knowledge has changed horses three times, with the usual losses accompanying such transactions, and has been thrown with his man, out of his gig by reason of his horse stumbling and smashing both shafts, all within the 12 months The slight smell of exploded petrol left behind in the street is not to be compared in disagreeableness to the aroma of the stable and all its offensiveness The habits of horses in the streets are particularly offensive before ladies, but because we are accustomed to these they are apt to be forgotten when weighing the *pros* and *cons* Once only have I been "hung up," and had I only had the "gumption" to lift up the seat and look at the battery I would have seen the spark flitting across from the coil into the battery again and so saved myself much wasted time and some of the above expenditure and have proceeded on my journey within the space of three minutes

I am, Sirs, yours faithfully,

East Molesey, Nov 25th, 1900 W. W HARDWICKE, M D St And.

P S — A man is indispensable to look after a motor car and he is useful also in his spare time about the house and garden

To the Editors of THE LANCET

SIRS,—It is, perhaps, natural that in a journal devoted to the "frailties of human nature," the morbid anatomy of auto-cars should find a place also Be this as it may, it appears tolerably certain that some of your correspondents have passed through sundry trying experiences There is one thing in particular that I take exception to, however, in Mr Lupton's letter in THE LANCET of Dec. 8th (p 1705) He says: " . *I know nothing of pneumatics*" and having made the admission that he is not qualified to speak from practical experience of them, he proceeds to warn all and sundry against them as "one having authority" Now, is this quite fair? Fortunately, my experience has been widely different from his, though I profess to be nothing but an amateur with the most ordinary capabilities and of quite average intelligence in matters mechanical Nevertheless, I am still using a motor tricycle over town and country roads, some of which are simply bogs of mud and wildernesses of newly laid metal I have travelled in various cars over 4000 miles, have never had a puncture, and have never kept a patient waiting Moreover, although riding a tricycle in the present weather, I can arrive anywhere without any outer crust of mud At this time of the year I find that I can only run about three miles for a penny, but in the summer I can manage 10 for the same sum I make these remarks after a year's experience of most kinds of motor-cycles and motor-cars I am, Sirs, yours faithfully,

CLAUDE A. P TRUMAN,
Honorary Secretary, Reading Automobile Club

Reading, Dec 8th, 1900

ERRATUM —In Mr Lupton's letter on "Motor-cars for Medical Men" published in THE LANCET of Dec. 8th (p 1705) the words "about 3*d* per mile" ought to be *0 3d* per mile

"HOSPITAL ABUSE A SIDE THAT IS SOMETIMES OVERLOOKED"

To the Editors of THE LANCET

SIRS —The concluding sentences of "A Hospital Surgeon's" letter in THE LANCET of Nov 3rd (p 1320), wherein he makes a tilt at general practitioners, seem rather unintelligible without some elucidation. Hos hospital abuse might affect a hospital surgeon's "right to a living" in some cases the following incident may show I was lately attend ing a young woman for anæmia and casually remarked that her eye, sight must be attended to, meaning to see to the matter myself when she was stronger However, she understood that I referred her to an oculist and presented herself at a certain eye hospital Though only belonging to the working class she was apparently "spotted" as a hospital abuser and was told by an official that she was not a proper case for gratuitous treatment and that she could not be attended to there. On inquiring what to do she was given the name and address of one of the hospital surgeons She attended at this gentleman's house and he very kindly agreed to see her for a fee of 5*s* at each consultation When I saw her she had paid him two visits, her pupils were widely dilated, but her eyes had not been finally tested By the time the affair was finished I daresay the hospital surgeon had earned h guinea. I am stating the facts as related to me by my patient and do not wish in any way to bring a charge against hospital surgeons, who have generally been most kind and courteous to me, at the same time these facts may throw a little light on the occasional connexion between hospital abuse and the "right to a living"

I am, Sirs, yours faithfully,

GENERAL PRACTITIONER (2).

Nov 3rd, 1900.

A CURIOUS POSITION.

To the Editors of The Lancet.

Sirs,—A and B are friends. A goes for a holiday and leaves his "friend the enemy" B to look after his work. *Inter alia* B is called to a case C, treats it, and on leaving at the end of about 10 days asks whether C is A's patient. The answer is: "Oh, no; I went on an emergency, was redirected to you, and refused my name at A's to prevent any bother. If I am anybody's patient I am D's (a practitioner at a distance)." A says B should take the fees. B says he thinks, under the circumstances, he should send in the bill and hand over the amount to A. Of course B cannot prevent C coming to him on another occasion. It may interest some of your readers to know what The Lancet thinks. I am, Sirs, yours faithfully,

Dec. 11th, 1900. B. A. H.

*** We think that B should send in the account and retain the fees. We also think that such excellent understanding between professional brethren is good for the welfare and dignity of all medical men.—Ed. L.

"MY CHEMIST."

A correspondent has sent us an advertisement put forth by an enterprising druggist. We reproduce a portion. Opposite to each stanza of the "poem" is a short description of some preparation or article supposed by the advertiser to be good for the particular pathological condition indicated in the stanza, the price being also stated.

When helpless in my cot I lay,
And screamed for bottle night and day,
Who sent the foods that made me gay?
My *chemist.*

When through my hard and swollen gum
The tardy tootsey would not come,
Who with his powders made things hum?
My *chemist.*

When headlong down the stairs I fell,
And bumped my brow and made it swell,
Who bandaged me and got me well?
My *chemist.*

Who helped me when I coughed and sneezed,
And my poor throat and bronchials eased,
And with sweet dose my palate pleased?
My *chemist.*

When on the pudding and the cake
Too vigorous assault I make,
Who takes away my stomach-ache?
My *chemist.*

And when, to keep a birthday up,
Too oft I drain convivial cup,
Who rights me with a pick-me-up?
My *chemist.*

And when I limp with many a corn
Into his shop with look forlorn,
Who heals my toes before the morn?
My *chemist.*

Who keeps my hair from turning grey,
And will not let my teeth decay,
And charms my wrinkles all away?
My *chemist.*

So with his praise where'er I go,
I'll burden all the winds that blow,
Till everyone around shall know
My chemist is

Here follows the name of the druggist. It hardly seems worth while for a man to spend five years and from £1000 to £1500 in getting qualified without getting some sort of protection from this kind of chemist.

"HAVE MATERNAL IMPRESSIONS ANY EFFECT ON THE FŒTUS IN UTERO?"

To the Editors of The Lancet.

Sirs,—So far as I am aware this controversy has hitherto consisted of the quotation of apparent instances of this marvel and of the reply that wars are not followed by an unusual proportion among the births of infants congenitally deficient in a limb and of similar counter arguments. If, however, any systematic and scientifically conducted experiments upon the lower animals have been tried already I should be much obliged by having my ignorance corrected.

I am, Sirs, yours faithfully,
Charles G. Stuart-Menteath
Upper Bedford-place, W.C., Nov. 23rd, 1900.

To the Editors of The Lancet.

Sirs,—In The Lancet of Nov. 3rd (p. 1266) there appeared an interesting article on the above subject by Dr. W. Duncan, but surely it scarcely requires the name of this eminent authority in order to convince the medical profession generally that so-called maternal impressions—the powerful ones, at all events—do exert an appreciable and visible result on the child in utero. The instances brought to light and published are now far too numerous to allow us to doubt what to my mind has been long an established fact. Probably there are few general practitioners who have not had at one time or another absolute evidence of the result of these powerful impressions. Two examples are clearly in my remembrance. A young mother had a boy a year old who had hypospadias. She was on a sea voyage with him and was so ill that she was not able to bath the child herself. A friend who was two months pregnant undertook the task for many days. When in due course of time her own child (a boy) was born he was found to be suffering from the same abnormality and exactly to the same extent as the child she had so diligently nursed. The second case is that of a lady friend of mine who in the early days of pregnancy had her eyes fixed often and earnestly on the well-known picture of "Bubbles" which, hanging in her bedroom, seemed to possess a peculiar attraction for her. In due time a beautiful boy was born who gradually developed into an exact image of the boy in the picture. But, further, it is my firm conviction that not only powerful maternal impressions which have their origin in physical causes may and do affect the physical form of the child, but that impressions which owe their origin to purely subjective thought in the maternal mind will induce a certain condition corresponding to, and on parallel lines with, the particular train of thought uppermost in the mind of the mother—in other words, a fixed and continuous maternal idea without the extraneous aid of a material object may have the same result as when the mother has the object or model continually before her physical sight. "Nothing is, but thinking makes it so." I "go one more" and maintain that a strong and continuous current of thought in a fixed line and having for its object the definite purpose of affecting the mentality of the child in a certain direction will not be void of result. The reason why so little proof in support of this statement is forthcoming is due to the fact that in the first place so few have the necessary concentration of thought; and secondly, because the great mass of people are still so crassly ignorant of the wondrous power of mere thought. Thought radiates from us all and at all times for good or evil; it moulds and alters matter and is transferred from one mind to another more or less easily. All this is now acknowledged and preached by scientists, philosophers, and religionists. Granted, then, that thoughts are actual (potent) things, and that maternal impressions produce impressions both physical and psychical on the unborn child, what a tremendous responsibility, what a power for good or ill, expectant mothers exert! As a matter of fact, they should hold firmly before their mental vision and carry out in their actual life all which is truest, highest, and best, so that their truer, higher, and better life will be reflected on the physical, mental, and spiritual being of their children. The consummation of this happy state of affairs would go far to alter the natural trend of hereditary evil influence, and given a father who lives a life of extreme "moderation in all things" and who has learnt that man is a spiritual being and not a mere animal, the resultant of mutual love (not lust), in spite of all hereditary tendencies, would blossom into something bright and beautiful. As it is, parents are guilty of a great crime in sending forth into the world countless helpless children who are nothing but the reflexes of their own animalism. I am, Sirs, yours faithfully,

Hastings, Nov. 26th, 1900. J. Stenson Hooker, M.D. Durh.

To the Editors of The Lancet.

Sirs,—In support of Dr. W. Duncan's proposition in The Lancet of Nov. 3rd (p. 1266) I can mention a case strongly pointing to the influence of maternal impression. About 15 years ago I attended the wife of a publican with her first child. The child when born was found to be completely minus a left hand, the forearm terminating in a rounded stump at the wrist. As soon as the birth was over the mother made anxious inquiries as to whether the child was "all right," but I had to tell her of the deformity, at which she expressed no surprise as she felt certain that something would be wrong. She then gave me the following account which I had no reason to doubt. One day in her early months of pregnancy while behind the bar two men came in for refreshment, one of them said that he had recently met with an accident necessitating amputation of his left hand; to support his words he uncovered the stump, which was scarcely healed, and exposed it to view. The sight, as the woman said, gave her "quite a turn" at the time. Now, one can scarcely accept this as a mere coincidence; the fact of the complete absence of the hand, and, stranger, the *left* one, coupled with the anxiety of the mother to know the condition of her child immediately after birth, negatives such a theory. I am, and for some time have been, a believer in maternal impressions, but I think such impressions would only operate in an early stage of fœtal development, as it is scarcely conceivable that, supposing a woman advanced to her middle or later stage of pregnancy, nature would deliberately amputate a hand already formed in utero. As to *how* nature works in such a case in building up the fœtus I offer no theory.

I am, Sirs, yours faithfully,
Reading, Nov. 27th, 1900. J. G. Braden, M.R.C.S. Eng., &c.

SATURDAY (22nd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (17th).—SOCIETY OF ARTS.—8 P.M. Prof. J. A. Fleming: Electric Oscillations and Electric Waves. (Cantor Lecture.)

TUESDAY (18th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.)—*Paper*:—Mr. F. T. Paul (Liverpool): Chronic Mastitis and its Relation to Tumour Formation (lantern demonstration). Card Specimens:—Dr. J. H. Drysdale: Broncho œsophageal Fistula.—Mr. Scholberg: Hæmorrhagic Pancreatitis with Fat Necrosis.

WEDNESDAY (19th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.)—8 P.M. Mr. Barton: Demonstration of Lantern Projection in conjunction with the Microscope.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

MONDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Mr. M. Morris: Consultation. (Skin.)

LONDON TEMPERANCE HOSPITAL.—3 P.M. Dr Addinsell: Some Abdominal Tumours.

TUESDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical.)

WEDNESDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—5 P.M. Clinical Lecture:—Dr. B. Yeo: The Treatment of Tubercular Peritonitis.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton)—4 P.M. Dr. Habershon: Emphysema.

THURSDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S Fenwick: Clinical Demonstration.

FRIDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Dr. H. Tilley: Consultation. (Throat.)

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. P. Parkinson: Case of Tricuspid Regurgitation.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.

A Lecture

ON

PULMONARY TUBERCULOSIS IN EARLY CHILDHOOD.

WITH SPECIAL REFERENCE TO ITS PREVENTION AND TO ITS DIAGNOSIS FROM OTHER WASTING DISORDERS.

Delivered at the Brompton Hospital on Nov. 21st, 1900,

By ARTHUR LATHAM, M.B., B.Ch. Oxon., M.R.C.P. Lond.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION.

Gentlemen,—Pulmonary tuberculosis in young children is a common disease—in fact, according to Baginsky, no less than 8 per cent. of all cases of pulmonary tuberculosis occur during the first ten years of life.

Etiology.

We have not sufficient time at our disposal this afternoon to make anything like a comprehensive study of this disease; still I think our best plan will be to glance briefly, in the first instance, at the etiology of the disease. Our knowledge on this part of the subject is not as definite as we could wish and forms an insufficient basis for the dogmatic assertions of the present day. There can, however, be no doubt that predisposition—the hereditary and acquired character of the soil—is a most important factor; thus healthy infants reared in tuberculous surroundings are not so liable to become infected as are the children of tuberculous parents, although these latter children may have been removed to healthy surroundings. As regards the infection itself there is also no doubt that in the vast majority of cases the tubercle bacillus reaches the lungs of young children either by an infected air-supply, or by an infected milk-supply. A very large proportion of pathologists hold that an infected air-supply is much the more common cause. Their view is mainly based on post-mortem evidence and on the fact that a tuberculous lesion of the bronchial glands is the most constant lesion found, and, further, that in the majority of cases the tuberculous process, viewed from the pathological standpoint, is more advanced in these glands, more especially on the right side, than it is elsewhere. I have studied a large number of reports giving relative statistics of the seat of the most marked lesions as observed at post-mortem examinations. These cases, which number over 3000 and which on the whole agree fairly closely, show that the above statement holds good. The deduction that tuberculosis of the bronchial glands is therefore always due to an infected air-supply does not, however, in my opinion necessarily follow.

In a lecture of this kind I cannot go into as much detail as I should wish or do more than give you a general idea of my own views and an outline of the evidence upon which these are based. I believe that an infected milk-supply plays a far more important rôle in the production of pulmonary tuberculosis than is allowed by most observers. I do not, however, in the least deny that air-infection is responsible for a certain proportion of cases. The bronchial glands are undoubtedly the chief seat of the disease, and this, I believe, is largely due to the fact that they form the most favourable ground for the growth of the bacilli, however these may be introduced, just as the valves of the heart may afford the best ground for other micro-organisms in infective endocarditis. My impression is that both in the adult and in the child the primary infection is by means of the lymphatic system, and up to the age of three and a half years is often dependent upon the tubercle bacilli, of an infected milk-supply, passing through either the upper or the lower portion of the alimentary tract, and eventually setting up changes in the bronchial glands. We know that the milk lies in contact with the upper part of the alimentary tract, which is common to the respiratory tract, or with the stomachic or intestinal mucous membrane. The tubercle bacilli do not rest here, but pass on by means of the lymphatics, leaving traces on their way, to the bronchial glands. Here they find what is usually called a nidus, and the glands undergo tuberculous changes of varying degree; the tuberculous process then not infrequently spreads from these glands to the lung tissue (1) by direct continuity; (2) by means of the lymphatics, but against the supposed lymphatic stream; (3) by ulcerating into a blood-vessel and in this way disseminating the bacilli all over the body; and (4) by ulcerating into a bronchus. When infection takes place by means of the respiratory tract it follows the same path—i.e., it passes through the lymphatics of the *upper* portions of the respiratory tract, and by means of them to the bronchial glands. It does not seem probable, on both anatomical and experimental grounds, that the air carries the tubercle bacilli by a tortuous path to the smaller bronchioles of the apex or other portions of the lung and then deposits them free to set up tuberculous changes. There is some evidence to show that the infection in the adult is also due to lymphatic absorption from the upper portion of the respiratory tract, and the observation that the apex of the right lung is affected more commonly than the bronchial glands may be due to the different lymphatic relations which obtain in the adult and in the very young child, differences which may in part be accounted for by the atrophy of the thymus gland. In this connexion I would remind you that, as in the adult the right apex is most commonly affected, so in the child the right set of bronchial glands is more commonly the seat of tuberculous disease than is the left.

If we argue on *a priori* lines we find that in adults, where, in the majority of instances, we undoubtedly have to deal with an air infection, the lungs are affected before, and more extensively than, the bronchial glands; consequently, if in children the primary affection is also through the air-supply we would expect to find a similar condition of things. We find the direct opposite; in fact, if post-mortem appearances in young children teach anything, they teach that tuberculous disease of the lungs does not often occur unless the tubercle bacilli first of all establish a hold on, and produce more or less advanced pathological changes in, the bronchial glands. The whole picture of adult pulmonary tuberculosis differs from what we find in the young child; in the former case the process is usually chronic and accompanied by a production of fibrous tissue, and an effort towards repair; in the latter the process is usually acute, there is seldom much fibrotic change, and the stage of cavitation and breaking down of tissue is comparatively seldom reached. In children we often find tuberculosis, sometimes advanced, in the bronchial glands, whilst the lungs are practically unaffected, a condition that is hardly ever met with in the case of adults. This difference in the course of pulmonary tuberculosis in the adult and in the child is more marked if we limit the age of the child to three and a half years, and may no doubt be partly accounted for by the more rapid growth of the tissues which takes place in the child. If we continue this *a priori* line of argument we may point to the fact that tuberculosis is, in numbers of cases, undoubtedly transmitted from the cow to her calves by means of the milk, and this in spite of the calves undergoing what is to all intents and purposes the open-air treatment. Or we may point to the striking fact that the curve of tuberculosis in children commences at the age of six months, reaches its maximum about the second year, and undergoes a remarkable fall between the third and fourth years—that is to say, tuberculosis is most marked at an age when infected milk would have most play, and becomes less frequent as the children begin to leave what may be called their milk life. Again, during the last 20 years the number of tuberculous cases has been very considerably diminished by better hygienic conditions in every period of life except early childhood. We know that, although great improvement has been made in our hygienic conditions, no improvement has been made with regard to the sale of tuberculous milk. We know that tuberculosis of cows is extremely common and we know that tubercle bacilli are to be found, not only in ordinary milk, but also in many specimens of condensed milk. We know, further, that in very young children, on account of the frequency with which they are fed, milk is practically always in contact with the upper part of the alimentary tract, and that it is an uncommon thing to perform a post-mortem examination on the body of a young child without finding semi-digested milk in the stomach or intestines; so that although the number of tubercle bacilli in a given sample of milk may not be great, yet such bacilli as there are have every opportunity for passing through the mucous membrane of the alimentary tract.

The whole question really turns on the circulation of the lymph. Our knowledge of this is very limited, for the circulation of lymph does not always follow the course we should expect, if we confined ourselves to our gross anatomical knowledge. In the case of animals it is a common thing to be able to watch the spread of tuberculosis by means of the lymphatics against the supposed direction of the lymphatic stream. Further, as I will point out in a moment, it is not always the case that the lymphatic glands in the immediate neighbourhood of the part with which the bacilli first come in contact are the first to be affected, nor is it true that the glands which show the most marked changes are necessarily the glands first attacked.

With regard to infection from the alimentary canal we know that tubercle bacilli can pass through the intestinal membrane without leaving any trace of their entrance and yet cause tuberculosis in more distant parts Much has been made of the absence of ulceration of the intestine, except when the tuberculosis of the mesenteric glands is extreme. My impression is, that when the tuberculosis of the mesenteric glands—which appear to be less susceptible to tubercle in the human subject than the bronchial glands—is extreme, it is due in many cases to a secondary infection back against the lymph stream. Further, it is a noticeable fact that tuberculous ulcerations of the bowels nearly always have a vascular rather than a lymphatic distribution. That other bacilli can pass through the intestinal walls is shown by the number of cases recorded of typhoid fever in which there has been no lesion of the intestine or mesenteric glands. Bollinger, many years back, showed that on injecting dilute solutions of phthisical sputum into the peritoneum and intestine the peritoneum remained sound in two-thirds of the cases, although the lungs became tuberculous. Durham, again, has shown that in cases of peritonitis the most important of the lymph channels which drain the peritoneal cavity are those which pass up along the anterior mediastinum, and that the glands which are affected are the anterior mediastinal group, of which the most constant are those in the first intercostal space. It is a common surgical experience in the case of other organisms to find lymph glands unaffected by the passage of the virus to favourable tissues It is not uncommon in malignant disease within the abdominal cavity to find that the only lymphatic glands secondarily affected are situated above the left clavicle A number of experiments which I have made confirm the statement of Delépine, that if guinea-pigs are inoculated in the leg, the seat of inoculation, the popliteal gland, the subcutaneous tissue from the popliteal region, and the spleen become infected at the end of four days, and that the superficial inguinal glands are not affected until the eighth day As the superficial inguinal glands are always infected before the deep set this means that with a primary infection of the leg the spleen becomes tuberculous four days—and here we are dealing with a considerable source of infection—before the glands in the inguinal region are affected.

With regard to infection by means of the milk-supply through the lymphatics of the upper portion of the alimentary tract I would point out that there is very considerable evidence to show that tubercle bacilli are frequently to be found in this region. To emphasise this, I may mention that in a careful investigation, by means of inoculation, of the central portions of the tonsils of 45 consecutive cases—the ages of the children varying from three months to 13 years—which were removed by operation or in the post-mortem room I was able to demonstrate the presence of tuberculosis in no less than seven cases, and in this I have merely confirmed the work of Dieulafoy, Gottstein, Woodhead, and many others. Bacilli may pass through the mucous membrane in this region without leaving any trace and so get to the deep glands of the neck From these the bacilli may pass to the bronchial glands, if we believe the authorities who assert that the deep cervical glands consist of two sets, one which runs along the carotid sheath and drains the mouth, palate, lower part of the pharynx, &c., and one which, lying in the supra-clavicular fossa, drains the upper set of glands and the lower part of the neck, and in addition communicates with the lymphatics of the axillary and mediastinal glands.

I have seen several cases where the primary infection was obviously in the tract common to respiration and alimentation. One of these cases was that of a young child, three months old; both tonsils were ulcerated; one was undoubtedly tuberculous; the glands on the same side of the neck were tuberculous; the bronchial glands were tuberculous, and there was general tuberculosis. The importance of this case lies in the fact that the mother of the child died from phthisis, that the child was fed practically all its life from the mother's breast, and that the most advanced disease was in the bronchial glands. Infection such as this may, of course, be due to respiratory causes and, in my opinion, often is. I am, however, convinced that the milk-supply is a more common source than is generally allowed, and though my evidence may not be convincing it is, I think, suggestive.

It is clear, then, even from our present knowledge that in taking steps to prevent pulmonary tuberculosis in young children we must not confine our attention to tuberculous sputum and hygienic surroundings, but must also insist that our food be free from tubercle bacilli There can be no doubt that this disease is a preventable disease and that, from a national point of view, our present methods for limiting its scope are far from what they should be.

CLINICAL VARIETIES.

The clinical varieties of pulmonary tuberculosis in young children are numerous, and very divergent classifications are given by the various authors on this subject. There is one fact, however, which is beyond dispute—namely, that the characters of pulmonary tuberculosis in very early childhood are radically different from those which obtain after the age of six years. Until the child is three and a half years of age tuberculosis is mainly dependent upon the infection of the bronchial glands and spreads from these glands to the lungs, rather than from the lungs to the glands as is the case in the adult. After the age of four years the lesions found are more and more comparable with the types we are familiar with in adult life. The varieties which are found up to the fourth year may be classified as follows:—1. Tuberculosis of the bronchial glands. This, of course, should not, strictly speaking, be included under the heading of pulmonary tuberculosis, but in view of what I have already said it is convenient to do so. 2. Miliary tuberculosis of the lungs. This may be dependent upon (*a*) a rapid primary infection without any discoverable old focus; (*b*) the rupture of a tuberculous bronchial gland into a blood-vessel with rapid dissemination throughout both lungs, more especially of the lower lobes; and (*c*) pulmonary infection secondary to other and older lesions, such as tuberculous disease of the testis, bone, &c. 3. Tuberculous broncho-pneumonia. This may be dependent on (*a*) the tubercle bacilli obtaining a hold upon a simple persistent broncho-pneumonia; and (*b*) direct spread by the lymphatics of the bronchi from a previously diseased bronchial gland. This third variety may go on, especially in the confluent form of broncho-pneumonia, to what Goodhart has aptly called cheesy consolidation, or it may in rare cases go on to a fibroid condition of the lung. In children who have reached the age of six years we may have in addition to any of these varieties: 4. Pulmonary tuberculosis which approaches the adult type but differs somewhat in its distribution and in the fact that there is a diminished tendency towards the formation of fibrous tissue.

TUBERCULOSIS OF THE BRONCHIAL GLANDS.

Uncomplicated tuberculosis of the mediastinal glands gives rise in the large majority of cases to no distinctive symptoms. As we have seen, tuberculosis of these glands frequently leads to secondary infection of the lung; these cases are associated with the usual constitutional symptoms, but in very many instances the glands may undergo changes, such as enlargement, caseation, calcification, fibrosis, and the like, without giving rise to any signs or symptoms during life. Thus it occasionally happens that the first indication of the disease is the perforation of a bronchus by a softened gland, an accident which not infrequently has a fatal result Enlargement of the bronchial glands, to a sufficient degree to cause symptoms, must be on a comparatively extensive scale. General symptoms, such as rise of temperature, may or may not be present; they may or may not precede the local ones which in the nature of things are mainly mechanical. In fact, in an uncomplicated case of enlarged tuberculous bronchial glands, if we get any signs at all they are those of a mediastinal tumour, and are usually more marked on the right side of the chest. Percussion may give dulness over the upper portion of the sternum or posteriorly along either side of the spine from the second to the fifth dorsal vertebræ. On auscultation we may have the tracheal or bronchial sounds transmitted to the ear and so may hear, more especially behind, cavernous, or, in marked cases, amphoric, breathing together with bronchophony; or if the enlargement is less pronounced exaggerated breathing together with prolonged expiration. It sometimes happens that we meet with a case in which there is compression of some part of a bronchus; we then hear either a very feeble respiratory murmur, or no murmur at all, over one lung or over one lobe of a lung. This sign, as Holt points out, is of great diagnostic value, but it is not often present. Large moist râles may be heard and we may be tempted to diagnose the presence of a cavity. Eustace Smith lays stress on the fact that even before the enlargement of the glands has become sufficiently great to cause obvious signs a venous hum may sometimes be heard over the upper part of the sternum if the child be made to bend the head back so that the face becomes almost horizontal. Other pressure symptoms vary according to the seat of pressure. Thus we may have pressure on the vagus or recurrent laryngeal nerves leading to paroxysmal cough, dyspnœa, and sometimes change of voice; pressure on the trachea or large bronchi causing dyspnœa; pressure upon the superior vena cava causing cyanosis and œdema of the face and upper extremities, with prominence of the veins and occasionally hæmoptysis or epistaxis.

DIAGNOSIS.

Enlargement of the bronchial glands due to tuberculosis must be diagnosed from enlargement due to other causes, such as syphilis, Hodgkin's disease, and malignant disease. These diseases are very much less frequent than tuberculosis; still in an individual case we have to depend upon the associated signs or symptoms of these diseases in other portions of the body. The paroxysmal cough sometimes suggests whooping-cough or asthma; these diseases may usually be excluded if we have definite evidence of a mediastinal tumour, or if we have the associated symptoms of tubercle, or in the case of whooping-cough by the characteristic whoop which sooner or later makes its appearance The alteration in the voice, the presence of the venous hum, or the existence of other pressure symptoms often gives us definite information.

MILIARY TUBERCULOSIS OF THE LUNG.

Miliary tuberculosis of the lung seldom occurs in young children except in cases of general tuberculosis. It is, however, these cases of general tuberculosis which are most frequently met with in very early childhood. The disease may occasionally be due to an acute infection without any old focus being discoverable, but it is much more commonly due to a primary infection of the bronchial glands or other tissue, and is caused by the dissemination of the tubercle bacilli by means of the blood stream. The symptoms may be divided under two heads: (1) general and (2) localising. The general symptoms always precede the localising ones; indeed, many cases show no localising symptoms at all, or only towards the closing scenes of the disease. The onset is usually insidious—the child gradually wastes, although he takes his food fairly well. This wasting is followed by general malaise, anæmia, want of appetite, and so on, but as a rule digestive disturbance is not a marked feature. Eustace Smith lays stress upon a slight pitting of the skin combined with a dry inelastic condition of the skin. Sooner or later, there are febrile symptoms; but the temperature is seldom above 102° F., and though irregular is not of the hectic type. So far, then, we have nothing characteristic of tuberculosis, and in fact, we have nothing upon which we can give a decided diagnosis. The progressive wasting with slight fever makes us suspicious, and our suspicions become a certainty when we find, as we do towards the later weeks of the disease, more or less definite localising symptoms. Thus we find hurried respiration, cyanosis of the lips and face, together with râles and diminished resonance all over the chest, or the presence of an occasional pleuritic rub; perhaps we may find some enlargement of the spleen, or more rarely of the liver, or evidence of the involvement of the bronchial glands, or it may be we discover tubercles in the choroid together with slight intolerance of light and other symptoms of meningitis.

DIAGNOSIS.

We have to diagnose this variety of tuberculosis from, amongst other things, simple debilitated conditions, from marasmus, typhoid fever, congenital syphilis, and in some cases malaria. The diagnosis is always difficult, and it is best to be always on the look-out for tuberculosis whenever we have to deal with a child in whom there is progressive wasting, but on the other hand to be in no hurry to make a positive diagnosis one way or the other. As long as there is an obvious and adequate cause for the wasting there is no necessity to make a diagnosis of tuberculosis. In the absence of definite or localising symptoms the surroundings, and, in fact, every available piece of evidence, must be duly weighed; a strong family history of tubercle or obvious tuberculous surroundings are in favour of a diagnosis of tuberculosis, just as an epidemic of typhoid fever in the neighbourhood is in favour of one of enteric fever. The demonstration of the presence of tuberculous deposit elsewhere, especially in the bronchial glands or testis, or the development of tubercles in the choroid, is decisive. Again, debilitated conditions and marasmus usually have a very definite relation to food and, unlike tuberculosis, are nearly always accompanied by diarrhœa and digestive disturbances; further, cases of marasmus respond very readily to an improved dietary. Typhoid fever may be distinguished by the more continuous fever, the presence of rose spots, together with an enlarged spleen, and, most valuable of all, by Widal's reaction, provided that this is obtained by a competent observer. Congenital syphilis may usually be distinguished by the family history, by the characteristic appearance of the child, and by the fact that other symptoms of syphilis are rarely wanting. The diagnosis from malaria must rest on the examination of the blood.

TUBERCULOUS BRONCHO-PNEUMONIA.

Tuberculous broncho-pneumonia may be due to a previous infection of the bronchial glands spreading into the lung by means of the lymphatics, or it may follow upon a simple broncho pneumonia such as we sometimes have in whooping-cough, measles, and the like The disease may be acute or it may run a more chronic course. In the acute cases there may be nothing in the symptoms or signs to justify a definite diagnosis of tuberculosis; but in many cases, towards the end, we have evidence of meningitis. In the more chronic form we may have an initial stage in which we have only the general symptoms of tuberculosis; this is followed by the development of pulmonary signs and symptoms. These vary markedly, often from day to day, and are essentially those of simple broncho-pneumonia, save for such differences as I shall point out in connexion with the differential diagnosis. The fever is moderate as a rule and in no case is it persistently high; there is seldom hæmoptysis, whilst definite signs of associated pleurisy are uncommon. The disease is rarely arrested, but reaches a fatal termination in from one to six months' time. Cheesy consolidation, especially of the lower lobes, or marked fibrotic changes, such as we find in the adult, may in some cases be the result of tuberculous broncho-pneumonia.

DIAGNOSIS.

The diagnosis of tuberculous from simple broncho-pneumonia is always difficult. Simple broncho-pneumonia may follow measles or whooping-cough and persist for some months, and we may be almost tempted in these cases to make a diagnosis of tuberculosis, only to find that all the signs and symptoms disappear. No disease teaches us so emphatically the necessity for the careful investigation of every detail connected with the case and the danger of making a diagnosis except after repeated examination. As a general rule tuberculous broncho-pneumonia has an insidious onset; in fact, if an attack begins with acute symptoms in a child who has enjoyed previous good health and has had the benefit of good surroundings the broncho-pneumonia is, nine times out of ten, of a simple form, no matter, as Holt in his excellent account of this disease insists, what the physical signs are, no matter how prolonged or irregular a course the disease may run. On the other hand, we must remember that in tuberculous broncho-pneumonia we often have intervals of what appears to be comparatively good health, and that the symptoms may abate for a time, only, however, to reappear in an aggravated form. The diagnosis here, as elsewhere, must rest largely on the associated conditions. The appearance of the child may help us, but it is seldom wise to place too much reliance upon this. It is, nevertheless, a fact that a copious crop of downy hair is frequently found on the backs of children who become tuberculous. Tubercle is strongly suggested if there is marked evidence of a tuberculous family history or of tuberculous surroundings; or again, if we find that the child has some other tuberculous lesion, such as testicular, spinal, or hip disease. Associated enlargement of the bronchial glands is convincing, as, of course, is any evidence of softening in the lungs. An occasional pleuritic rub may help us. Little stress can be laid upon the character of the temperature; still if this is taken at frequent intervals we may find comparatively large excursions which are more suggestive of a tuberculous than a simple form of the disease. Our difficulties may be solved if we can obtain the sputum. Young children, however, mostly swallow their sputum—in fact, any child under six years of age who expectorates profusely is probably suffering from pulmonary tuberculosis. It is worth while to mention that the sputum may sometimes be obtained by giving the child a gentle emetic; failing this it will sometimes be found possible to pick out little masses of purulent material from the fæces; these represent the swallowed sputum, and on examination may yield definite evidence of tuberculosis.

Pulmonary Tuberculosis Resembling the Adult Form.

I have already said that after the age of four years, and still more after the age of six years, the type of pulmonary tuberculosis conforms more and more with what we commonly meet with in adult life. We find, however, some characteristic differences. There is not the same tendency for the tuberculous process to begin at the apices of the lungs and to extend gradually downwards which we find in the adult; there is not the same tendency to the formation of fibrotic tissue. Extensive excavation is less common; hæmoptysis and laryngeal complications are seldom met with; pneumothorax is rare; and, finally, the child not infrequently succumbs to meningitis or other acute infection. Remember that in children physical signs are not to be depended upon as strictly as in adults; for instance, a cracked-pot sound may be of no importance at all.

Prognosis.

The question of prognosis in any form of tuberculosis is always difficult, and this is especially true in the case of children. The immediate outlook is naturally grave in uncomplicated tuberculosis of the bronchial glands when there are marked pressure symptoms. When the associated conditions are not so prominent both post-mortem observation and experience teach us that we may expect most excellent results in many cases from careful treatment, provided that this treatment is carried out under medical supervision for a sufficiently protracted period of time. We must never forget that tuberculosis of the bronchial glands is a fertile source of further infection, and in these cases we must constantly be on the alert for any symptoms which may indicate that the lungs are becoming involved, and consequently must pay more attention to any apparently trivial and incidental illness in such a child. The prognosis in miliary tuberculosis of the lung—which is due to a blood, and therefore extreme, form of infection—is most grave. Cases usually reach a fatal termination in from three to six weeks after the onset of acute symptoms. In the tuberculous form of general broncho-pneumonia, which is so largely due to infection through the lymph stream, the prognosis is again a grave one. Acute cases may terminate fatally in a few days or they may run on for from two to six weeks. In the more chronic cases, as a rule, the patients gradually become worse, sometimes regularly, sometimes irregularly, and they die in from two to six months. When the condition in this form of the disease is comparatively circumscribed the outlook is much more favourable and the reaction to suitable treatment is much more marked. Cases in which the process starts during the acute stages of measles or of whooping-cough are unfavourable; when, however, the tubercle bacilli become grafted on a simple broncho-pneumonia which follows an attack of measles or pertussis the outlook is a brighter one. Always be guarded in your prognosis, for you will occasionally meet with patients who seem hopelessly ill but who eventually get well and possibly remain well; on the other hand, you will see cases in which the disease appears to have become quiescent but in which the patients succumb to some acute exacerbation following upon what is often thought to be a trivial and incidental illness. In the adult type of pulmonary tuberculosis in young children the prognosis is more favourable. Children who come under medical care in the initial stages of the disease in very many instances do remarkably well. This clinical experience is supported by the frequent observation after death of healed tuberculosis. In some cases the disease may apparently heal completely, but sometimes some trivial incident causes the disease to light up again and to follow an acute course. Therefore do not be in a hurry to pronounce that the disease is cured, and always insist that your cases be kept under medical observation and direction for a long period of time. In later stages of the disease I do not think that the prognosis in children is as good as it is in older people, and no doubt this is largely due to the absence of fibroid and localising change. In making a prognosis you must, as in the adult, take into account the family history and the surroundings of your patient; his general appearance, constitution, and previous history; and you must search carefully for tuberculous lesions elsewhere.

Treatment.

The first thing to do in the case of a child who is threatened with tuberculosis or who has developed definite signs of the disease is to take care that there is no further possibility of infection either through the air or through the food-supply. The measures to be adopted are the ones you are familiar with in the case of an adult patient; it may, indeed, be said at once that our treatment of tuberculosis in young children must follow the general lines of our treatment of this disease in the adult. The treatment of miliary tuberculosis, general tuberculous broncho-pneumonia, and advanced forms of tubercle is mainly symptomatic. In the case of a child who seems to be threatened with tuberculosis, or who has definite symptoms of bronchial infiltration or of the commencement of tuberculous changes in the lung comparable to what we see in the adult, we must be guided by the following principles. The most important is attention to detail; nothing is so small but that it should receive attention. The patient must have fresh air with plenty of sunlight, a sufficiency of good, nourishing, digestible food; precautions must be taken against catching cold and against becoming tired. This last is very important and is often overlooked, but you will find not infrequently that the advance made by a child, after the expenditure of much anxious care on your part, is altogether neutralised because he is allowed to over-exert himself. On the other hand, the child must be made as hardy as possible.

With regard to climate, the chief necessities are an equable temperature and a dry soil. Large variations of temperature and a moist atmosphere are harmful; high altitudes are better avoided; cold, if dry, is preferable in many cases to warmth. Details as to a proper form of clothing must not be forgotten; careful attention must be paid to any apparently trivial illness which may arise, and the condition of the tonsils and the throat must be carefully scrutinised. You will find in many cases that small amounts of stimulants do good, and that massage often leads to considerable benefit. Of drugs, the most beneficial in children is cod-liver oil; this is really a food and may sometimes be replaced by cream. Too much must not be given; indeed, in dealing with tuberculosis of young children our best plan is to begin with small doses in the case of nearly all drugs and then gradually to increase the daily amount. Give half a drachm of cod-liver oil twice a day to a child of two years of age and gradually increase the amount. From time to time inspect the stools to see that this fat is absorbed; if it is not, diminish the dose or give in addition some pancreatic preparation. If a child will not take the oil in this way give it in the form of an inunction. Of other so-called specifics, preparations of creasote, commencing with half-minim doses, guaiacol, calcium chloride, and the hypophosphites in gradually increasing doses, are often of undoubted benefit. The syrup of iodide of iron or vinum ferri are useful preparations in anæmic cases and in uncomplicated cases of enlargement of the bronchial glands. Symptoms must be treated as they arise, on the principles with which you are already familiar. In advanced cases our efforts must be directed towards the relief of distress and finally towards euthanasia.

Notification of Infectious Diseases.—At the meeting of the Torquay Town Council, held on Dec. 5th, it was agreed, on the recommendation of the Sanitary Committee, that the medical officer of health should be authorised to pay half a guinea for each notification received from medical practitioners of cases of infectious diseases existing on farms sending milk into Torquay.

ON SOME DISAPPOINTMENTS OF SURGERY.[1]

BY D'ARCY POWER, F R C S ENG ,
SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN CHELSEA ,
ASSISTANT SURGEON TO ST BARTHOLOMEW'S HOSPITAL

THE art of surgery has improved so rapidly during the last quarter of a century that we are perhaps a little too much inclined to consider a surgical operation as the simplest and most certain method of curing a patient In many cases the operation actually cures, in other cases it relieves the particular condition for which it was undertaken, whilst in others, again, the result by no means fulfils the expectations of the surgeon or even of the patient These surgical disappointments are quite distinct from surgical calamities, the number of which can be lessened by care, though no foresight can wholly abolish them from the practice of the most competent operator I mean death during trivial operations serious hæmorrhage, unavoidable injuries to vital structures and the physiological peculiarities of individual patients which embarrass the surgeon to the detriment of the patient With such calamities I have nothing to do at the present time They occur with greater or less frequency in the practice of every surgeon and are necessarily independent of the care which he bestows upon his art They have been treated most ably by Sir James Paget in an essay on the "Calamities of Surgery" published in his volume of clinical lectures I am concerned rather to day with the minor unsatisfactory results of operations—the true surgical disappointments, not the surgical mishaps—disappointments which are due to two main causes Either the surgeon did protest too much, in which case his patient is disappointed, or else he carried to extreme the wholly admirable teaching of Hippocrates, *Μη βλαπτειν, Non nocere*—Not to do harm It is the surgeon who is then disappointed that his timidity prevented him from reaping the full benefit of the operation Every surgeon sings the praises of his art and the benefits to be derived from operation, but such songs of hope and success should be sung in the early days of spring and in the long warm evenings of summer The winter afternoon of a December day in London is, I venture to think no unfitting occasion to consider some surgical disappointments for by knowing the cause we may sometimes avoid the disappointment I propose to illustrate my remarks by cases which have come under my own observation, though I have very little doubt that many of my hearers will supply parallel instances and we may thus obtain texts for a very profitable discussion

Beginning, as we should do, with the early days of life, there are few operations more often performed than those of circumcision and for hare-lip yet there are few which may give more disappointing results The aim of a perfect circumcision is to remove just so much of the foreskin as is necessary to liberate the glans penis and to avoid removing so much as to leave the patient a '*curtus Judæus*' Such a perfect operation is rare but I do not recollect that the difficulties were ever pointed out to me The disappointment which I have most often felt is that the cut surface of the prepuce has contracted adhesions to the glans—an accident which is especially likely to happen when the penis is ill developed If the mother is careless and the child is not seen for some days after the operation the adhesions may become so dense that it is impossible to break them down and the child is then in a worse condition than he was at birth I was somewhat troubled at first by the occurrence of this accident, but now I make it a practice to see the patient at short intervals, and if there is any tendency to retraction of the glans I adopt the ritual plan of pulling back the foreskin until the corona is exposed and keeping it thus retracted by passing the penis through a slit in the gauze dressing The constriction of the penis by the prepuce sometimes causes a little swelling of the penis but I have never seen any ill results follow In the operation for hare lip the bugbear of the surgeon used to be the formation of a notch at the bottom of the scar in the lip This error has now been so long brought under our notice and so many plans have been devised to avoid it that I venture to think it never occurs at the present time. A much more common fault is the neglect of accurate apposition of the two red edges of the lip, which gives rise when the healing is complete to an unsightly irregularity in the red border of the lip Every precaution, therefore, must be taken at the time of the operation to get the two upper margins of the mucous surface of the lip exactly upon the same level and to secure them by passing the first suture at that point There is no difficulty in obtaining accurate apposition in many cases, but the proceeding is by no means easy when the cleft is uneven and one side of the lip is higher than the other

The recurrence of adenoids is a fertile source of disappointment to parents whose children are so unfortunate as to suffer from these growths The operation for their removal may be carried out with perfect success, but the predisposition remains Adenoid tissue grows quickly and the original condition is soon reproduced if reliance be placed too entirely upon operative measures Too much, therefore, should not be promised as a result of removal, for there is a growing disinclination amongst the more observant mothers to submit their children to operation

In all these instances the disappointment can be avoided if due care be taken but I well remember the chagrin with which I watched a baby upon whom I had operated for an imperforate anus where the rectum opened into the vagina The bowel ended in a well defined cul de sac which it was easy to open from the perineum, but do what I would the aperture closed and the fæces continued to come through the vaginal opening The recto vesical fistula was well defined and the defective front wall of the rectum was nicely rounded off by mucous membrane continuous with the back wall of the vagina, yet the parts were too small to allow of complete closure and any incomplete union of the edges soon broke down I do not know how such a disappointing result can be avoided except by waiting until the patient has attained to years of maturity

The greatest disappointments undoubtedly occur in connexion with abdominal operations and in no operation perhaps more often than in those carried out upon the kidney This, indeed, is so well recognised that in many cases the surgeon contents himself with speaking of an exploration of the kidney and is content to treat the condition which he finds when the kidney is exposed Before exposure it is often impossible to detect the presence of one or more renal calculi when they are small and embedded in the substance of the kidney, nor is it always easy to distinguish a renal inflammation caused by a stone from one produced by tubercle Even when nothing is found to explain the symptoms from which the patient suffered an exploratory operation often does good and the patient is freed from pain or discomfort in a most remarkable manner, This satisfactory result is due in part to the effect of local blood letting, in part to the freeing of the kidney from adhesions, and in part to the division of the tense and perhaps chronically inflamed tissues surrounding it

Disappointments sometimes await the surgeon and the patient after an exploration of the kidney Such an one occurred lately to me A female patient had long suffered from obscure symptoms of renal disease which had quite prevented her from following her occupation and seemed to point to the presence of a stone I exposed the kidney opened it on the convex border, and passed a probe along the whole length of the ureter in order to assure myself that no stone was lodged in it The patient did excellently for some days after the operation and the lumbar incision healed perfectly by first intention On the eighth day, however, her temperature suddenly rose to 105° F and she had a sharp attack of pyelitis This has become chronic, and whereas her urine before the operation was clear and free from pus it is now pus laden On the other hand she is free from pain and is able to perform her daily work in comfort She is satisfied, but I am not, for I suppose that the operation set fire to a latent tuberculosis The patient, however is sometimes disappointed when the surgeon is satisfied—as in the case of the very troublesome people who complain of numbness or hyperæsthesia along the course of the last dorsal nerve after a lumbar exploration of the kidney Again both patient and surgeon may be equally disappointed—as happened in the early part of this year when I had operated for the relief of a movable kidney. I anchored it with three stout kangaroo tail tendons passed through the whole thickness of the lumbar wall deeply into the substance of the kidney, and again through the body wall with the exception of the skin. For the sake of extra security I kept the patient in bed for a month instead of the usual three weeks, and by so doing I undid the good which she had received. She increased rapidly in weight, and whilst she was lying in bed her kidney once again detached itself, the result. I suppose, of a great increase of the perinephric fat. In other renal cases, again (but of these I have fortunately had no personal experience hitherto), much disappointment results from the formation of a small but troublesome fistula, although the operation is perfectly successful in every other way.

---

[1] A paper read at a meeting of the Harveian Society of London on Dec 20th 1900

The formation of fistulæ is by no means confined to renal operations. There is no surgeon with any considerable experience in abdominal work who has not had occasion repeatedly to study their formation after laparotomies which at first promised success in every way. I have had them after excision of the spleen, after strangulated hernia, after removal of the appendix, after ovariotomy, and after opening the gall-bladder. They occur, of course, under two conditions—immediately after the operation when the escape of pus or other fluid has prevented the wound from healing, and, at a period more or less remote from the operation, when the wound has healed soundly. A fistula of the first kind can hardly be called a disappointment, as its occurrence is anticipated from the time the wound is left to granulate. The more remote fistulæ are really disappointing; for what can be more troublesome than that a wound which has healed well and soundly should inflame after a week, a month, or even a year, at first without any apparent cause, until at length a small abscess forms at or near the scar and a ligature presents? It is not always easy to explain why this happens after the longer intervals, though I have a shrewd suspicion that the cause is the same in every case and that it is due to the use of an infected ligature. The infection may be quite mild and may be situated so deeply in the strands of a stout silk ligature that the leucocytes have first to find their way into the depths of the ligature, where they become infected, die, and so cause the abscess. If this be the cause and the only cause the cure is plain—boil your ligatures. I am not quite sure, however, whether the general health of the patient has not something to do with the formation of an abscess in the more remote cases, for in the interval between the healing of the wound and the first sign of inflammation the patient appears quite well and there is no evidence of any septic absorption.

Internal strangulation of the bowel, like hernia, is fertile in disappointments. There is the wretched condition in which, after the strangulation has been relieved, the patient, as Paget says,[2] "is too exhausted to be conscious of relief and goes on dying though he be carefully fed and nursed." I had a miserable example of this a few months since in the person of a fine and otherwise healthy young man, aged 21 years, who had been allowed to suffer from intestinal obstruction beginning suddenly a week before he was sent to the hospital. I opened his abdomen and found that a Meckel's diverticulum had attached itself to the rectum and that several feet of intestine had passed under the arch thus formed and had become strangulated. There was no difficulty in relieving the obstruction by dividing the diverticulum, but the bowels were so paralysed and the septic intoxication was so deep that he died in spite of all that careful nursing could do for him. The post-mortem examination showed that he was well anatomically, for I had removed the whole diverticulum and the scar in the intestine scarcely showed. The moral taught by this case is that which nature is never tired of pointing. An operation at the earliest possible moment is demanded imperatively in every case of acute intestinal obstruction.

I have met with the same disastrous disappointment after relieving an intussusception. The following is such a case. A child, aged eight months, who had been ailing for some time, began to suffer suddenly from the symptoms of intussusception on April 7th. I opened the abdomen 13½ hours after the onset of the acute symptoms and reduced an ileo-colic invagination. The child passed a moderately good day on the 8th. His abdomen was flaccid, there was no vomiting, but his bowels were not relieved. On the night of the 9th the patient had two good motions, the first of a reddish-brown colour, the second of a natural yellow colour. The food was well taken on the 10th and the temperature fell to normal. The child appeared to be progressing favourably and I had good hopes that he would recover, for he had two more natural motions during the day. At 8 P.M. on the 10th (69 hours after the operation) the child again begain to vomit a brownish fluid. He refused his food, became drowsy and cold, and fell into a condition of profound collapse. The abdomen was supple, the wound was aseptic, but the abdomen gradually distended until coils of intestine could be seen moving beneath the abdominal walls. Matters went from bad to worse, and on the 13th the abdominal wound was gaping widely and the intestines had prolapsed. They were replaced under an anæsthetic, but the child died on the following day. The necropsy showed that the small intestines were distended with flatus to within 12 inches of the ileo-cæcal valve. The distension suddenly stopped at this point, although there was no visible cause for the arrest either outside or within the intestine or abdomen. The colon, like the lower part of the ileum, was collapsed. The thickened ileo-cæcal valve projected a short distance into the cæcum. The valve and the mucous membrane for about two inches beyond it were congested, but there was no intussusception and there were no visible signs of peritonitis. Microscopical examination of a portion of the ileum which had been invaginated showed a slight extravasation of blood into the whole circumference of the submucous coat. The glands, the adenoid tissue, the circular muscular coat, and the serous coat appeared to be healthy in every respect. The individual fibres of the longitudinal muscular coat stained less deeply than they should do, and in many cases appeared to have undergone some degenerative change, for they were unduly granular and more highly refracting than usual. The extravasation of blood in the dilated part of the intestine immediately above the point of constriction was slight, but was distinctly visible between the serous and the muscular coats. The layer of external longitudinal muscle presented changes similar to those described above as occurring in the invaginated portion of the gut. The other coats of the dilated intestine were normal.

The case is instructive, for it shows that the symptoms of obstruction may re-appear and even progress to a fatal issue although an intussusception in a young child has been completely reduced. The operation in this case was not difficult, no undue force was used, the intestine was not injured, there was no peritonitis visible, and the wound at first showed every disposition to heal kindly. The digestion of food and the normal motions of the intestine for two days after the operation showed that the alimentary canal was able to carry out its physiological functions. Yet in spite of this the patient fell into a condition of what the older writers called "ileus paralyticus"—a condition which we now believe to be always the consequence of peritoneal infection or septicæmia. It is sometimes found after the successful reduction of a strangulated hernia or the successful reduction of a volvulus of the colon, and it is marked by increasing feebleness, passing into collapse, undiminished tympanitic distension, increasing vomiting, and usually, says Mr. F. Treves, but by no means necessarily, a continued inability of the bowels to act. The meteorism was not due in this case to any obstruction, and although the pathologist found no evidence of peritonitis I fear the child died from septic poisoning.

Operations upon the vermiform appendix afford so many surgical disappointments that I think that it is never wise to promise the patient or his friends too much beforehand. The great and immediate disappointment at the time of the operation is inability to remove the appendix, either because it cannot be found or because its attachments render it unsafe to complete the operation. In two of my operations for removal of the appendix it has been quite impossible to find the appendix by any reasonable amount of dissection. The appendix in each case seemed to be packed away behind the cæcum and was apparently lying parallel with it in such a dense mass of adhesions that even a prolonged search failed to find it. In another case the appendix was attached to the bladder in such a manner that its tip had ulcerated through the walls and had caused the appearance of pus in the urine. It was considered inadvisable in this case to attempt any removal of the whole appendix, which was therefore divided, the distal end being left attached to the bladder and the proximal end being removed. The patient made a good recovery and the urine was soon free from pus. Small abscesses are often found in separating the adhesions which have formed round an inflamed appendix and in these cases it is not unusual to find that the wound does not heal by first intention but that a troublesome sinus is left. In other cases the scar of a wound which has united kindly at the time of the operation afterwards yields and a ventral hernia is produced, which is as disappointing to the surgeon as it is annoying to the patient.

---

[2] Clinical Lectures and Essays, p. 149.

Mental disturbances following upon a surgical operation sometimes form a remarkable series of surgical disappointments, as they often occur in patients who have passed through life without any suspicion of mental unsoundness, though the event shows them to have been in a state of unstable nervous equilibrium. The disturbances show themselves in many ways. The following cases have come under my notice during the last year. A woman, aged 60 years, came under my care with cancer of the liver associated with attacks of intense pain. She was perfectly rational and collected when I saw her at home, though her husband said that she was very obstinate and had a most domineering temper. She was admitted into hospital for an abdominal exploration, when the novelty of her situation and the bustle of a large ward at once caused her mind to wander. I waited a day or two until she had recovered herself, and then I exposed the gall-bladder and set free many adhesions which had formed between the surface of the liver and the parietal layer of the peritoneum, and thus gave her great relief from pain. Another case was that of a worthy domestic servant, aged 35 years, who had lived in the same situation for many years and had always seemed to be of average mental calibre. I tied many varicose veins in both legs and, amongst others, the internal saphenous vein high up in the thigh. The wounds had been closed, dressings had been applied, and the patient was ready to leave the operating theatre, when the spica bandage was suddenly soaked with blood. The dressings were hastily removed, the wound in the groin was re-opened, and a large hole was found in the femoral vein. The vein was at once exposed and ligatures were passed round it above and below the rent. The vein was then divided, its walls being little thicker than a piece of tissue paper, and the wound was again closed. All the wounds healed by first intention and the patient afterwards declared that the leg the femoral vein of which had been tied was the more satisfactory of the two. She showed, however, a decided inclination to the formation of bedsores and her mental condition was clearly impaired from the time of her recovery from the anæsthetic. She was garrulous and constantly talked nonsense. Another case was that a man, aged 59 years, but looking much older, whose right upper jaw I removed on account of a carcinoma which had invaded it. Directly after the operation the patient began to suffer from hallucinations and it was necessary to have him watched continuously to prevent his escape from the ward. He died a month later from septic pneumonia. These cases of mental disturbance are always distressing, for they occur as often after slight as after severe operations, and they are said to be especially frequent in the practice of gynæcologists and ophthalmic surgeons. They are quite distinct from delirium tremens and traumatic delirium and the failure of power often seems to be general, for when mental disturbance occurs the wounds very frequently suppurate even when every care is taken to prevent interference with them by the patient. Dr. S. R. Macphail[3] says that in his experience at the Derby Borough Asylum he has seen 40 cases of insanity occurring after surgical operations in a total of 990 admissions. 13 of the cases were those of men and 27 were those of women. In only nine was there any hereditary predisposition to insanity. On an average the mental symptoms first showed themselves upon the tenth day after the operation. 24 of the patients recovered, eight became chronically insane, and eight died, four of the deaths being caused by malignant disease. Sir William Mitchell Banks[4] in his recent Lettsomian Lectures has also called attention to the occurrence of acute mania after operations on the breast and points out that the mental confusion and hallucinations depend upon an unstable mental condition and not upon septic absorption or upon the use of such drugs as iodoform and carbolic acid.

Perhaps the most disastrous, but at the same time some of the best-known, surgical disappointments occur in connexion with injuries to bones. Who is there who has not seen trouble after a Pott's fracture which has been well set shortly after the accident? The slight eversion and the accompanying flatness of the foot are always causes of annoyance to the patient. But even when there has been a seemingly good result and time has been allowed to obtain firm union the original deformity may recur if the patient be unusually heavy or if for any reason the amount of repair has been miscalculated. The remedy is an easy one in theory, though it is sufficiently difficult to apply it in practice, for it consists in restraining the natural desire of the patient to get about and to attend to his business at the earliest possible opportunity. It is far better for him, and in the end shorter, to wait until the union is thoroughly sound.

Colles's fracture is fruitful in disappointments and especially when it occurs in old people. Union takes place readily enough, but the connective tissue surrounding the joint becomes so infiltrated with the products of chronic inflammation as to leave a stiff and useless wrist for many months after the accident. It is of the utmost importance, therefore, to shampoo the injured part and to begin passive movement at the earliest possible time, and this is usually on the fourth day.

Non-union is more than disappointing after the fracture of a long bone, for, in children at any rate, it leads to the most disastrous results since it is often necessary to amputate the limb. There is no means of knowing what cases are likely to end in this manner, though the absence of crepitus or muffled crepitus in an unimpacted fracture may lead to the suspicion that some of the soft tissues intervene between the ends of the bone. When there is no mechanical obstacle the tendency to non-union can be reduced by taking care to keep the two fragments of bone absolutely at rest. Thus Mr. Pickering Pick recommends that the shoulder as well as the elbow should be fixed during the repair of a fractured humerus, and in a child I certainly prefer not to trust to a plaster-of-Paris case when both bones of the leg are broken, unless the patient can be carefully watched. It too often happens in the out-patient practice of hospitals that a plaster case is applied to the broken leg of a child, who is then sent home. The mother or relative omits to bring the patient back to the hospital for a fortnight or three weeks and allows the child to sit in a chair swinging his legs or permits him to crawl about the floor. The plaster case becomes soft or the injured leg wastes a little from disuse, and the case, which fitted well enough at first, soon becomes too loose. In either case the two fragments of bone move upon each other in such a manner as to prevent the production of callus and non-union is the result. The remedy is simple, for the child has only to be kept under observation, and non-union, at any rate in children, is a very rare accident.

The formation of a conical stump after amputation is always annoying and may be disastrous to the reputation of a surgeon. It is well recognised that conical stumps rarely occur in adults if sufficient care be taken to fashion the flaps properly and to saw the bone at a sufficiently high level. Yet they do occur sometimes when every precaution has been taken and more particularly after primary amputations in largely built and robust individuals whose muscles and connective tissues shrink much more quickly than their bones atrophy.

It is sometimes quite impossible to prevent the formation of a conical stump in children and young adults, especially after amputation through the upper arm and the leg. The humerus, the tibia, and the fibula chiefly grow in length from their upper epiphyses. It may happen, therefore, after amputation that these bones grow more rapidly than the surrounding tissues and the end of the stump may taper more and more until ulceration takes place and the bones protrude. Such a conical stump is seen occasionally after an intra-uterine amputation.

Injuries of nerves are another source of disappointment in connexion with fractures either on account of the pain or because of the paralysis which is produced. Implication of the musculo-spiral nerve in a fractured humerus, compression of the ulnar nerve after an injury to the elbow, and injury to the external popliteal nerve from a fracture involving the neck of the fibula have given me considerable trouble at various times. The results of operative interference in these cases have never been very satisfactory, for though the patient is relieved he is never as well as he was before the accident and he is certainly never as well as I should have liked to see him.

Operations for the relief of chronic neuralgias are always most disappointing, for the cerebral cortex seems to become so impressed with the sense of pain that as soon as one source is removed another is made. Two such cases are under my care at the present time, the one a woman with coccygodynia, whose coccyx was fixed almost at a right angle with her sacrum, so that it pressed inwards upon the rectum; the other a man with violent pain referred to the ends of the right fifth nerve. The woman is convinced that her pain, if anything, is worse since I removed her coccyx; the man, who had a few weeks' relief after I had cut away a part of his inferior dental nerve, now suffers agonies in the terminal branches of the superior division.

---

[3] Brit. Med. Jour., 1899, vol. ii., p. 751.

[4] THE LANCET, March 24th, 1900, p. 844.

Dislocations are perennial sources of disappointment, more especially when they involve the larger joints, such as the hip. The text books on surgery teach us so glibly about the methods of reduction by manipulation that it is only by bitter experience we learn that there is another side to the question—that some dislocations cannot be reduced, that others can only be partly reduced, and that others, again, when they have been reduced, leave a useless joint. When it is impossible to reduce a dislocation it is better, I think, to wait for a time and to see what provision nature will make, rather than proceed to the performance of any surgical operation, but if the pain is very severe and the limb is very useless operative interference at an early period seems to be fully justifiable.

These, gentlemen, are some of the disappointments which attend the practice of surgery. I have no reason, however, to suppose that we have a monopoly of them as general surgeons. The ophthalmic surgeon, I know, has his troubles after operations for strabismus, or when a troublesome piece of capsule mars the effects of an otherwise perfect operation for cataract. The orthopædic surgeon is not always contented with the results of his operations for talipes. The gynæcologist too often lands himself in a sea of trouble after an apparently simple operation; whilst the general practitioner himself is soon disillusioned of the glamour of his profession and is apt to become the most disappointed of any of us, for he sees the failures of all. But in spite of this we should agree with Goethe that the most successful man is he who cares least for disappointments, though he is ever learning from his failures.

Chandos-street, W.

OBSERVATIONS ON COMPRESSED AIR ILLNESS.

BY FREDERICK R. WAINWRIGHT, M D McGILL,
M.R.C.S. ENG., L R C.P. LOND.,
MEDICAL OFFICER TO THE BAKER STREET AND WATERLOO RAILWAY TUNNEL WORKS.

THE opportunities afforded for the observation of the pathological effects of high atmospheric pressure have been relatively very few and the testimony of every additional observer may be of value in aiding in the elucidation of a rather obscure subject. It is for this reason that I venture to publish these remarks, which embody my experience and the conclusions at which I have arrived as the result of that experience. It is not my purpose to discuss the physiological effects of compressed air on the human economy, for in my opinion observations along this line made during the progress of an engineering work of great magnitude would not afford trustworthy results, there being so many factors apart from the actual air pressure which would tend to render one's conclusions inexact. Neither is it possible within the limits of this paper to give an account of the history of the use of compressed air in engineering operations from the invention of the diving bell in the sixteenth century up to the present time. A very complete account of the subject has already been given by Dr. E H. Snell in his excellent little book on "Compressed Air Illness," together with his own experience while acting as medical officer to the Blackwall Tunnel.

It seems probable that in the future compressed air will be used to a much greater extent than it has been in the past and the knowledge as to the best means of reducing to a minimum the suffering inseparable from this class of work will be of value not only to the workmen employed but also to the employers themselves. At the Baker-street and Waterloo Railway tunnel works we had, considering the pressures employed and the length of the shifts, remarkably few cases of illness. The opinions which I hold as to the reason of this comparative immunity I will endeavour to express later.

It is a matter for regret that so much work under compressed air has been done in which no medical records were kept, and this is not only the case with undertakings carried out many years ago, for even in so recent a work as the St. Clair Tunnel, under the St. Clair river in America, there seem to have been no accurate medical records, though I gather from a general description of the tunnel that there was much illness and that several deaths occurred. Among the best records of the last 30 years are those of Dr. Jaminet of the St. Louis Bridge and Dr. A. H. Smith, the medical officer at the construction of the Brooklyn Bridge. But while admitting the value of their observations I totally disagree with their conclusions as to the pathology of the condition and also as to some of the factors which are instrumental in its production.

For the better understanding of the conditions under which the men employed in the compressed air worked it will be well for me to give a short description of the tunnel. It was only in a certain portion of the tunnel that the use of compressed air was necessary—that part of it which ran through the ballast in the bed of the river Thames. The tunnel was reached by two shafts sunk through a staging erected in the river, the top of the tunnel being a few feet below the bed of the river. Before the shield had reached the ballast the river-crossing section of the tube was cut off from the other part by a brick diaphragm into which a lock, with doors closing airtight, was fitted. At each end of the lock was a tap for the purpose of admitting the air from the pressure section when entering or for allowing it to escape into the other portion of the tunnel when leaving the compressed air. It was possible to fill the lock up to 30 pounds per square inch in one and a half minutes and to empty it at the same pressure in one and three-quarter minutes.

A few remarks regarding the astonishing rise in temperature when "locking-in" may be of interest. I have noted the mercury rise, when "locking-in" with a "full tap" at 30 pounds pressure, from 60° F. to 115°. During "locking-out" I have seen it fall from 90° to 46°. Foley assigned a very important place to this cold misty atmosphere in the production of the illness. While quite admitting that such sudden variations in temperature are not advantageous I do not consider that they play the smallest part in the etiology of the condition. The air was conducted from the air compressors to a large tank beneath the water, passing through this before being delivered into the tunnel, the idea being to cool it to some extent. I doubt whether this plan was very effectual, for on several occasions I took the temperature of the air as it left the supply pipe and found it to vary between 110° and 120°, according to the speed at which the air compressors were running. As it passed along the tunnel and escaped at the face it cooled to about 85°.

The pressures in the tunnel varied with the state of the tide and the nature of the ballast met with. As a general rule at low water the pressure was from 23 to 25 pounds per square inch, at high water from 28 to 30 pounds, and on several occasions it was as high as 35 pounds per square inch It is to be remembered that these figures refer to pressures over and above the 15 pounds per square inch normal atmospheric pressure.

VENTILATION.

When it became necessary to use the air pressure the river-crossing tunnel had already progressed so that the face or shield end was 123 feet from the lock. Thus, to begin with, there was a fairly spacious chamber for the men to work in. The ventilation during the whole time that the shield was in the ballast was excellent, on account of the very free escape of air through the gravel at the face. I was in the habit of estimating three times daily the amount of air pumped into the tunnel, and found that it gave an average amount per hour of about 6000 cubic feet for each man. This amount was well distributed, for, on my recommendation, the supply-pipe emptied just at the lock, thus causing the air to sweep from one end of the tunnel to the other in order to escape at the face. Before this was done the air at the face had shown 0·06 per cent. carbonic acid gas and at the lock end 0·09 per cent. After the alteration in the pipe the whole tunnel showed the same amount, varying between 0·06 and 0·07, which degree of purity was maintained until Oct. 4th. On this latter date, the shield being again in clay, the air could not escape at the face and we had to depend on artificial ventilation. The percentage of carbonic acid gas rose at once to 0 081, then to 0·1, and could not be brought below 0 075 till Oct. 28th when the compressed air was dispensed with. How this difference in purity affected the amount of illness I will point out further on. The tunnel was lighted by electricity which, by obviating the necessity for the use of candles or gas, materially improved the conditions. The men were divided into three gangs, each gang doing a "shift" of eight hours. The men working in the face, and who were exposed to wet, were provided with clothes which they changed on leaving the tunnel and which were dried before being again used. A well-warmed room was also provided for the use of the men to induce them to rest before going home, but of this they never took advantage. Hot coffee was supplied to them on leaving the tunnel and was much appreciated by them. I have no doubt that it was of benefit after the cold atmosphere of the lock. Smith states that it appeared to relieve to some extent "the nervous prostration which marked the return to the open air." I was never able to detect the smallest sign of nervous prostration in the men coming off a "shift," so I cannot offer any opinion as to the value of coffee in the condition. Before allowing any man to commence work in the compressed air I subjected him to a physical examination, paying particular attention to the condition of his heart and arterial system. Very stout men and those advanced in years were not accepted, though considerable latitude may be allowed in these conditions Alcoholism, I consider, should debar a man from this class of work, and I rejected any man who on presenting himself showed signs of recent excess. Of the 120 men passed 88 had previously worked in compressed air, while 32 had no previous experience The youngest man was 19 years of age and the oldest was 52 years, the average age being just over 30 years.

In all, during a period extending from May 23rd to Oct. 28th, 1900, 47 cases of illness due to work in compressed air came under my treatment. These cases occurred in 40 different men, two having three attacks each and three having two attacks each. In these figures I include only those cases which were of sufficient severity to call for treatment. I do not believe that a single man escaped a slight twinge of pain at some time or other to remind him of the nature of his occupation, but these were very evanescent and they cannot be dignified by the name of illness.

PATHOLOGICAL EFFECTS.

The pathological effects of compressed air are manifested at two distinct times and are due to entirely different conditions. The first class is purely mechanical and is noted when going into, or when actually in, the pressure The second class comprises those symptoms which are only seen after leaving the compressed air.

The symptoms consequent upon mechanical pressure *per se* consist of pains in the ears, frontal and maxillary sinuses, and in carious teeth. Pain in the ears is common when "locking-in" for the first time, especially if the pressure be rapidly admitted, but is rarely met with afterwards unless there be a condition of "cold in the head," pharyngitis, &c., which interferes with the normal patency of the Eustachian tubes. The pain has all grades of severity, from a mere sense of oppression to the most acute agony. It is, of course, due to the fact that if the Eustachian tubes are blocked the pressure outside the drum is greater than that in the middle ear and the membrane is pushed forcibly inwards. If the Eustachian tube remains closed and the pressure be sufficiently great rupture of the tympanum may ensue. This actually occurred in two cases which came under my notice, in one of which I myself was the patient. The injury had no permanent ill-effects in either case. Apart from actual rupture the relative vacuum in the middle ear brings about a congestive condition of its lining membrane which, according to Dr. Snell, may result in inflammation which may be followed by suppuration. I had no case of this kind brought to my notice. The pains in the frontal and maxillary sinuses do not call for special mention. In my experience they were very infrequent, and I never observed them apart from a catarrhal condition of the nasal mucous membrane. In these cases, during "locking out," there may be a discharge of blood-stained mucus from the nose. The foregoing conditions are, as before stated, dependent on mechanical causes, and cannot well be considered as part and parcel of compressed air illness. Furthermore, in my experience, they never occurred apart from an abnormal condition of the mucous membrane of the nose or pharynx, therefore I cannot regard them as a necessary accompaniment of exposure to an atmospheric pressure above the normal.

In the second class are those symptoms which are only manifested after leaving the pressure. These symptoms, though perfectly distinct from each other, are, I believe, all due to the same underlying pathological condition. The most frequent and characteristic manifestation is pain, usually occurring in the joints, less frequently in the muscular structures of a limb. In only one of my cases were the muscles of the trunk affected. The pain may be confined to one joint or may be present in two or more joints, the latter condition being the more usual one. In my series of cases the knee was the only joint to be affected singly and this only occurred in four cases out of the 47. The knee-joint is more frequently attacked than all the other joints combined, and in 19 of my cases the knees were the seat of pain apart from any other manifestation, and in 16 cases pain in the knees co-existed with other symptoms. Next in order of frequency came the elbow-joint which was affected in 11 cases, then the shoulder with seven cases to its credit. The hip joint was the seat of pain in five cases, the wrist in three cases, and the ankle in one case. Any number of joints may be simultaneously affected. The pain varies from a mild ache to the most severe suffering, and in well-marked cases I know of no condition which produces a greater degree of physical agony. The patient becomes pallid and perspires freely, the pulse is hard and rapid, and unless he is possessed of a considerable amount of self-control the man cries and groans. The pain has been described to me as "a feeling as if the joints were being twisted off" or "as if a dog were gnawing a bone" If untreated the pain may disappear in five or six hours or it may persist with diminished intensity for several days or even weeks. The onset of the pain may be at any time after coming out of the compressed air. In some cases it comes on immediately, in others not for several hours. The longest interval in my own cases was five hours, but Dr. Snell gives notes of a case in which 14 hours elapsed between leaving the pressure and the appearance of the pain. As a rule not more than two hours elapse. I have almost invariably found that the sooner the symptoms appear after leaving the pressure the more severe they are. Swelling is not common in the joints, but is invariably present if the pain is situated in the muscles. I have never found any tenderness present, even vigorous friction relieving, rather than aggravating, the pain. I am aware that on this point my experience is directly contrary to that of most other observers. Epigastric pain and vomiting may occur and are usually very severe and refractory to ordinary treatment. In well-marked cases the pain is intense and the vomiting is persistent. This condition only occurred in about 10 per cent. of my cases and Dr Snell only found it in a small percentage. On the other hand, Dr. Jaminet describes it in 78 per cent. of his cases and Dr. Smith in 24 per cent. Formication or itching of the skin followed by redness may occur; only one such case came before my notice

Cerebral symptoms.—Headache and giddiness are not uncommon as following exit from the compressed air. In four of my cases giddiness was very pronounced, the patients reeling and falling down. Pain in the head is not necessarily present but may exist along with the giddiness. Vomiting is not uncommon in these cases, being cerebral in character and quite apart from any gastric disturbance. Visual troubles, such as diplopia and flashes of light, may be present. As a usual thing these symptoms are of short duration and they yield very quickly to appropriate treatment. Dr. Snell gives notes of nine cases of vertigo occurring after exit from compressed air. The onset in all the cases was sudden, and in six of them some amount of deafness was present, tinnitus occurring in four cases. In some of these cases the vertigo lasted for many months. No case of auditory vertigo due to working in compressed air came under my notice, so I am unable to speak of it from personal experience.

Paralysis.—Paralysis only occurred in one of my cases, the condition being one of paraplegia with involvement of the bladder and rectum. Dr Snell only had two cases at the Blackwall Tunnel, while in New York Dr. Smith observed it in 15 per cent. of his cases, and at St. Louis it was present in 61 per cent. Dr. Smith says that the paralysis most often affects the lower half of the body but may include the trunk or arms. According to him pain may or may not be present in the limbs even when tactile sensation is lost. In my case the only pain felt was on each side of the spine in the lower lumbar region.

Death.—Death is not a very uncommon sequence of work in compressed air, and it may occur suddenly on leaving the pressure or after previous paralysis or other symptom. Out of 76 cases of illness at St. Louis Bridge there were 12 deaths. Dr. Smith had three deaths in 110 cases, and four deaths occurred in sinking the caisson for the Londonderry new bridge and this with a pressure of only 28 pounds. As far as I can discover, the Forth Bridge and Blackwall Tunnel were the first works using high pressures which were put through without a fatality. At the Baker-street and Waterloo Railway Tunnel works we had no fatal case.

DIAGNOSIS.

When we consider the devious workings of that peculiar statute known as the Employers' Liability Act it becomes a matter of some importance that these cases should be carefully diagnosed and differentiated from other conditions having somewhat similar symptoms. It must also be remembered that the pains may possibly be assumed. the man hoping thereby to be a financial gainer. I agree with Dr. Snell that the most important points in the diagnosis are the time and manner of the onset. Physical signs being rarely present in any form, there is little else to go upon. Personally I would not admit a case to be due to compressed air where twelve hours had elapsed from the time of leaving the pressure till the onset of the symptoms. Rheumatism, osteomyelitis, and arthritis deformans are not likely to be mistaken for the joint pains of compressed air illness. The absence of any rise of temperature in the latter, together with its sudden onset and freedom from physical signs, will serve to distinguish it. I here insert a note on one of my cases which was interesting, not only from the point of view of diagnosis, but also because I am unable to find a similar case recorded in any of the writings on compressed air illness which I have been able to consult.

CASE 1.—The patient, a strong, healthy man, aged 50 years, rather inclined to be stout, had worked in compressed air before coming to the Baker-street and Waterloo railway tunnel works and had been employed at these works for some time. On August 29th, 1900, he came out of the tunnel at 6 A.M. after doing an eight-hour shift. At about 6.30, when he reached home, he felt a pain "in the front of his chest." He at once got very short of breath and felt very distressed though the pain was very slight. He had a feeling of impending death. He managed to return to the stage, stopping every few yards to get his breath, and he reached there at 10 15 P.M. and I at once saw him. He was then in great distress and was unable to speak more than a few words at a time. His face was very dusky. I have never seen more severe dyspnœa. The pulse was 120 and very feeble and the respirations were 45. I at once auscultated his chest and found a most peculiar state of affairs. Posteriorly there was nothing abnormal and the supraclavicular regions were negative. But all over the front of the chest a most unusual sound was heard, audible throughout the whole respiratory cycle. I have never heard anything like it before, consequently I am unable to give any comparative description of it. It was very harsh and creaking, sometimes tearing, in character, and most marked between the third and seventh costal cartilages on the right side. I then percussed the chest with absolutely negative results, and on applying my stethoscope immediately afterwards I found that all the auscultatory phenomena had disappeared. There was no cardiac displacement and there were no murmurs, but the sounds were very distant and feeble. As the man was evidently in a serious condition I at once put him into the medical lock and re-compressed him up to 18 pounds, at which point all dyspnœa had gone and he felt perfectly well. This pressure was allowed to "leak out" in 70 minutes and the patient came out of the lock feeling quite well. There was no return of the symptoms. No physical signs could be discovered after coming out.

Now, in this case there might have been considerable difficulty in the matter of diagnosis. The mode of onset certainly pointed to compressed air as the causative factor, but it was hardly possible to be certain until the immediate cure of the condition by re-compression removed all doubt as to the nature of the trouble.

ETIOLOGY.

The one essential for the production of this illness is, of course, a sojourn in an atmospheric pressure above normal. This, however, does not in itself cause any of the symptoms given above but only brings about the conditions necessary for their development after the subject returns into a lower pressure. It must be thoroughly understood that there are no manifestations of this illness so long as one remains in the compressed atmosphere; it is my belief that a man might live in a pressure of three atmospheres for an indefinite time without necessarily experiencing any ill-effects. In addition to the essential cause there are others factors which are very important, the first two in order of importance being the length of stay in the pressure and the amount of carbonic acid gas present in the condensed atmosphere. The influence which the latter has upon the former of these two factors is so great that it is hard to separate them in considering the share which each one has in the production of the illness. Dr. Snell has enunciated a law that the amount of illness varies inversely with the amount of fresh air supplied. With this I thoroughly agree, and when considering the length of time spent in the pressure the carbonic acid gas factor must be thought of, and, within certain limits, it may be laid down that the time which may be spent in the pressure without resulting bad effects depends very largely on the percentage of carbonic acid gas present.

Leaving aside the question of ventilation for the moment and assuming the percentage of carbonic acid gas to be a fixed quantity, then the length of stay in the pressure is, in my opinion, the most important accessory in the etiology of the disease—far more important than the time employed in leaving that pressure. At the Baker-street and Waterloo railway tunnel there was no case of illness occurring in a man who had not been at least three consecutive hours in the pressure. In addition to the regular eight-hour workers there were many men, such as fitters, plate-layers, gangers, &c., who spent variable periods of time in the condensed atmosphere, so that I had an excellent opportunity of proving this point.

Regarding the relative importance of the length of stay in the pressure as a factor in the production of the disease opinions have differed. Dr. Jaminet recommended short shifts at the St. Louis Bridge, but nevertheless he considered the time spent in "locking-out" as of primary importance. According to Dr. Snell, Mr. Eads, the chief engineer of the bridge, was the first to call attention to the fact that the length of stay was more concerned in the production of the illness than the rapidity of "locking-out." Dr. Smith attached great importance to the length of stay in the pressure and he formulated the law that the danger is as the degree of pressure to which the person has been exposed multiplied by the duration of the exposure. At the Brooklyn Bridge the pressures rose gradually, with the depth of the caisson, from 18 pounds to 36 pounds per square inch, the length of the shifts being four hours at first, gradually reduced to two hours as the pressure increased. Even with these short shifts Dr. Smith reports 110 cases of compressed-air illness as occurring in four months. At the Baker-street and Waterloo railway tunnel, where eight-hour shifts were worked, there were only 47 cases in five months. At first sight these figures would appear to show that the length of stay does not play a rôle of any importance in the production of the illness. But it is precisely here that the carbonic acid gas factor comes in and proves itself to be of such importance. At the Brooklyn Bridge caisson the air contained 0·33 per cent. of carbonic acid gas, while at the Baker-street and Waterloo railway tunnel, as has already been stated, the percentage up to the last three weeks was kept at from 0·06 to 0·07. Dr. Smith seems not to have considered ventilation as of any importance, and he makes the remark that "this amount (0·33) of vitiation was found not to affect the men unfavourably." In my opinion it was just that vitiation which was responsible for his large number of cases. No doubt it also had much to do with the "nervous prostration" which he observed in men coming out of the pressure. It is true that Dr. Smith had a larger number of men than were employed at the Baker-street and Waterloo railway tunnel, but had we worked in four-hour and two hour "shifts" instead of in "shifts" of eight hours the number of our cases would, in my opinion, have been insignificant.

Dr. Snell claims to have been the first to point out the relationship between the amount of illness and the fresh air supplied to the compressed air-space, and he gives some very interesting tables from his experience at Blackwall in support of his views. My own observations on this point were necessarily limited as the air-supply was large and constant up to nearly the end, but the figures I am able to give are, I think, sufficiently striking. From May 23rd to Oct. 4th, with an average of 6000 cubic feet to each man per hour, there were 34 cases, say, eight cases per month. Following this with an average of 1700 cubic feet to each man per hour there were 13 cases in a period of 12 days. I found also that the cases occurring during the latter period came on sooner after leaving the pressure and were of greater severity than those occurring during the time of good ventilation.

I do not assign a very important position to rapid "locking-out" as a cause of the illness, though I am firmly of the opinion that could this process be sufficiently prolonged it would probably altogether prevent subsequent symptoms. But in order to achieve this result three-quarters of an hour at least would be required to be spent in coming out of a pressure of 30 pounds to the square inch, and this, from an economic point of view, would be impracticable. Some observers have laid down very precise mathematical rules as to the length of time to be spent in reducing given pressures, though it is difficult to see on what these rules are based. Dr. Smith says that five minutes should be allowed for each additional atmosphere, while Dr. Jaminet gives one minute for each additional six pounds of pressure. At the Baker-street and Waterloo railway tunnel it was possible to "lock-out" of 30 pounds pressure in one and three-quarter minutes during the first three months. After that the exit tap was altered so that to leave the same pressure required at least six and a half minutes. This alteration did not in the slightest degree affect either the number or the severity of the cases.

There are some minor predisposing causes which have been assigned different degrees of importance by various authorities. Among these newness to the work, age, alcoholism, and obesity are the chief. With regard to an old hand being less liable to compressed air illness than a newcomer opinions differ. Dr. Smith strongly adheres to this view, though admitting that some very severe cases occurred among old hands. Dr. Snell does not admit the increased liability of a new hand to the disease, but says that it is very difficult either to prove or to disprove it. Personally it is a point upon which I am uncertain, though my figures would tend to show that a man is more susceptible when he first begins this class of work than after having been engaged in it for a greater or less period. Of 88 men who had previously worked in compressed air 25 were affected, or 28 4 per cent, while of 32 men who had had no previous experience of such work 15 were affected, or 46 8 per cent. Of the 40 men who were affected, in 16 the illness occurred after the first "shift"—that is to say, in 40 per cent.

Age has been considered to be an important factor, the amount of illness varying in proportion to the age. The only statistics which I can find are those given by Dr. Snell from his own experience, and covering, as they do, a large number of men of all ages they have an especial value. He concludes that below the age of 20 years men are singularly exempt from this illness; between the ages of 25 years and 45 years the liability to illness does not vary to any great extent, but is about twice as great as between the ages of 20 years and 25 years, and that after the age of 45 years the liability increases very considerably. My own conclusions, though based on a much smaller number of men, agree with those of Dr. Snell, and I am of the opinion that young men stand compressed air better than do those of more advanced years. But it is only in the very young ones that a marked immunity is observed, the amount of illness from 25 years to 40 years not varying much according to the age.

Fulness of habit has been noted by many observers as specially predisposing to the untoward effects of compressed air. Dr. Smith made a strong point of this in his essay on caisson disease, and he gives figures in support of his views which show that of 86 cases of illness the spare men were responsible for 28, the medium for 22, and the heavy for 36. He adds, "Considering that among labourers below the age of 45 (and none were above that age) the class described as heavy are very much in the minority these figures are sufficiently striking." As I excluded all men who were conspicuously stout I have not been able to form any opinion from observation on this point. But I am quite sure that the cases occurring in moderately large men were neither more numerous nor more severe than those in men of light build.

Alcoholism has been said to strongly predispose to compressed air illness, a man who has been drinking heavily being frequently a sufferer, and certainly some of my most severe cases occurred after a too free indulgence. But this is a point upon which it is hard to come to a satisfactory conclusion, for the reason that, with two exceptions, all the men used alcohol, the majority freely, so that no comparative statistics could be obtained. But I am inclined to the view that alcohol is a predisposing factor of considerable importance.

Muscular exertion following upon exit is insisted on by Dr. Jaminet as being of importance in bringing about the symptoms, and he noted a diminution in his cases when the men were drawn up instead of reaching the top of the caisson by climbing the ladders. Dr. Smith also supports this view, but admits that he has no figures to offer. At the Baker-street and Waterloo railway tunnel the men were drawn up in a cage and were forbidden to mount the ladders, but always hurried away as soon as they reached the top. Two of the men used bicycles, riding home a distance of six miles immediately after coming out of the compressed air, neither of them having an attack throughout the whole five months. I have never been able to see any reason for supposing that muscular exertion after exit increases the liability to the illness though I do not deny the possibility of its being so.

PATHOLOGICAL THEORIES.

Very many theories have been put forward in an endeavour to explain the manner in which compressed air causes the symptoms for which it is responsible. But possibly even more surprising than their number is the fact that so many of these elaborate theories do not in any way harmonise with the observed symptoms and conditions. In many cases it appears as though, so long as the theory happened to be vague and abstruse, its sponsor was perfectly indifferent as to whether or not it could be reconciled to the facts. The symptoms have been variously ascribed to exhaustion, hæmorrhage, rheumatism, congestion of various parts, carbonic acid gas poisoning, and supersaturation of the blood by the compressed atmosphere. It would be quite impossible within the limits of this paper to give, with any sort of completeness, the arguments put forward by those who happen to pin their faith to one or other theory. All that can be done is to examine them in a general way and to attempt to point out where, in my opinion, they appear to fall short.

The exhaustion theory is based on the hypothesis that an increased metabolism follows a stay in compressed air owing to the greater amount of oxygen present. This is purely hypothesis, for, as Dr Snell points out, no experiments have as yet proved that any such increased activity of the vital processes does occur. On the contrary, many observers have arrived at the conclusion that there are no grounds for such a belief. Personally, though my observations were clinical and not experimental, I have not been able to find any reason for holding that work in compressed air is associated with increased metabolism. Appetite has been said by many to be increased and Dr. Smith says in regard to this that it "seems to point to an increased waste of tissue to be supplied by a greater consumption of food," though he would not accept the explanation as conclusive, believing that this could not occur without increased temperature. I do not presume to doubt those who say that appetite is generally increased, but in my own experience I have not found such to be the case. I carefully questioned some 30 of the more intelligent of the men regarding their appetites when working in compressed air. Only two said that they ate more, the majority that they noticed no alteration, while a few stated that they did not use as much food. Neither is there any rise in temperature. But let us admit, for the sake of argument, that this increased tissue metamorphosis does occur, can we account for the symptoms in this way? Dr. Jaminet held an affirmative opinion, and in fact his treatment consisted altogether of stimulants and nourishment, but by what process of reasoning he arrived at this conclusion it is beyond my power to conjecture. My own opinion so thoroughly agrees with that of Dr. Snell that I cannot do better than quote his own words: "......But if severe and often excruciating pain in the limbs, and elsewhere, paralysis of the legs, bladder, and rectum, and sudden death, are each and all to be ascribed to 'exhaustion,' this term must surely be employed in some more special and technical sense than is usual." Furthermore, this theory offers no explanation of the fact that the illness depends largely on the amount of carbonic acid gas present—i.e., the less oxygen the more illness. Neither does it account for the curative action of recompression in these cases nor for the complete absence of symptoms so long as one remains in the compressed air.

The theory that carbonic acid gas produces the illness by direct poisoning requires no more refutation than the statement that the symptoms of poisoning by this gas bear no resemblance to those met with in compressed-air illness.

Congestion of the brain, spinal cord, and other organs is considered by Dr. Smith in his essay on caisson disease, by Dr. Moxon in the Croonian Lectures in 1881, and by many other observers to be the cause of this illness. Dr. Smith says that "it is probable that the pathology of this disease is not entirely uniform in all cases," but does not doubt that congestion is the chief element in it. But in his further elaboration of this theory he assigns congestion the chief and only place, although not bringing forward a single fact which goes to prove his contention. He begins by making the statement that the centres will be congested at the expense of the periphery in a compressed atmosphere, and having laid down this law in no uncertain manner deduces a second law "that firm and compact structures will be congested at the expense of those more yielding," and on top of this a third law "that structures within closed bony cavities are congested at the expense of all others." Now it is the easiest thing in the world to deduce a law from a statement, the difficult matter being to be quite certain that the statement is correct. Does the blood, as Dr. Smith says it does, pass from a place where the pressure is greater to one where it is less, and if so, where does it go to find a place which is not already filled with matter, either fluid or solid, or how can it increase the tension in these central parts when, as Dr. Snell well puts it, "blood-pressure is everywhere raised and every one part of the body presses with greater force on every other part"? The only compressible parts are the free gases in the alimentary canal and I can corroborate Dr. Snell's opinion that this potential space is principally occupied by the abdominal wall being pressed in, as, from my own observations, the latter is the case when one goes into a compressed atmosphere. If the blood under pressure leaves, say, the periphery of a limb, how does it do so except as a result of compression of that limb? Dr. Smith says that solid structures resist compression. How, then, are the fluids contained in the solid structures going to be driven out of them? It would seem as reasonable to say that one might by compressing a glass bottle squeeze water out of it without altering its shape. In order for the pressure to act on the blood it must necessarily do so by compressing surrounding structures. But in compressed air there is not the least evidence of this taking place. The limbs are not altered in the least degree either in size or in shape. Dr. Smith says that superficial veins are obliterated and that the skin is anæmic, and he even makes the statement that the hands are shrunken and shrivelled owing to the blood being squeezed out of them. Now I have repeatedly examined the men while in the pressure in order to ascertain to what extent I could corroborate these observations of Dr. Smith's. In my experience I can emphatically say that these phenomena did not occur. The skin does not become anæmic, the veins are not effaced, nor are the hands altered in appearance in the slightest degree. But on other grounds it is difficult to admit the engorgement of the internal structures assumed to occur by the exponents of this theory. Is it reasonable to suppose that a man could work, and work hard, for eight consecutive hours with his brain, spinal cord, liver, &c., in such a congested state, and could do his work without the slightest feeling of discomfort and keep it up, on and off, for years without discoverable ill-effects? To my mind it is most unreasonable. Again, how does this theory agree with the actual symptoms of the illness? Dr. Smith holds that the vessels both in the congested and anæmic parts will suffer from a loss of tone which will bring about a lowering of tension in the vascular system. He also appears to believe that while in some cases the pains are of local origin in most cases they are spinal. I believe all the joint and muscular pains to be local and not spinal in origin. And in any case will the fact that the vessels are suffering from loss of tone be sufficient to give rise to a pain of such intensity? Can the case of cardiac dyspnœa to which I have referred be put down to congestion, spinal or otherwise? Although Dr. Smith did not use recompression as a therapeutic measure he was impressed with the fact that when a man returned into the pressure the symptoms vanished. He says that he would expect recompression to be of special value in "paralysis not dependent on extravasation of blood." But if paralysis in common with the other symptoms were dependent on congestion, how would re compression be of service? It would simply bring about congestion of the cord once more. Dr. Smith does not attempt to explain why he thinks re compression would act beneficially, and if one were held to the congestion theory it could not be satisfactorily explained.

In the *New York Medical Record*, 1890, Dr. Corning attributes the symptoms to anæmia of the cord. But it is only in exceptional cases that there are any symptoms which can properly be referred to the cord, and it is perfectly justifiable to suppose that the same cause is at the bottom of all the symptoms, depending altogether for its effect on the part of the body upon which it acts. Finally, neither of these theories explain why carbonic acid gas should be a factor in the production of the illness only second in importance to the pressure itself.

Supersaturation of the blood.—Now we come to the theory which has for its foundation the law of Dalton, which enunciates that fluids absorb gases in direct proportion to the pressure. Water dissolves at 10° C. and under one atmosphere pressure oxygen 0·028 part, nitrogen 0·014 part, carbonic acid gas 0·90 part. It is held that during a sojourn in compressed air the blood becomes charged with the atmospheric gases proportionately to the pressure and that after exit, the pressure being removed, the blood is no longer able to hold the air in solution and it may become free in the vessels and surrounding tissues and thus give rise to the various symptoms met with. We have in this argument an adequate explanation of the symptoms not only of joint pains but of paralysis and other manifestations. I am of the opinion that the case of cardiac dyspnœa which I have recounted can be explained very reasonably as being due to extravasation of air into some situation where it caused pressure on, and consequent embarrassment of, the heart, though what that exact situation was I confess that I am not able to say. Now regarding the absorption by the blood of gases under pressure it has been shown by Bert that such absorption does take place although not exactly according to the rule laid down in the law of Dalton. Hoppe found that in animals killed by a rarefied atmosphere there were bubbles of free air in the blood. He concludes that the same effect takes place in passing from a condensed to a normal atmosphere. Bucquoy considered that in a compressed atmosphere the amount of gases absorbed by the blood increased in accordance with physical laws and that on decompression gas must escape and may cause in some cases joint and muscular pains and hæmorrhages. Dr. Snell as a result of his observations strongly supports this theory of supersaturation of the blood. Now what arguments are there against the tenability of this theory? I have carefully observed every case of compressed air illness which came under my treatment and have considered the conditions which appear to bring about an increase or a decrease in the number of cases, and I have been unable to find any fact which cannot be reasonably explained if we accept supersaturation of the blood as the underlying cause of the symptoms. Dr. Smith, it is true, objects to this theory on the very insufficient grounds that frequently the symptoms do not appear until several hours after leaving the pressure, whereas, in his opinion, if the symptoms were produced by free bubbles of air in the blood-vessels this condition should be at its maximum at once after leaving the pressure and should give rise to the symptoms immediately. His second objection is that the fact of the "comparative immunity from danger which results from repeated exposures to compressed air" could not be explained if the action were due to purely physical causes. He says: "The obstruction of the vessels described by Bert is a condition of which the system could never become tolerant by frequency of repetition." The first objection may be answered by pointing out that the disengagement of the air from the blood is not an instantaneous process, and that very many of the fine bubbles may have to collect before even a capillary vessel can be blocked, and, as Dr. Snell further points out, a still greater collection must take place before stretching and rupture of the capillaries can ensue. Regarding Dr. Smith's second objection it may be said that the comparative immunity acquired as a result of repeated exposures to compressed air is as yet not proven, though personally I am inclined to the opinion that some degree of immunity may result. But even if this be admitted I can see no reason why the vascular system should not adapt itself to this condition equally as well as to the condition of congestion described by Dr. Smith. Probably in many of the cases the vessels do not rupture, but the air passes through them into the surrounding tissues. Why should not the vessels acquire a resistance to this or to rupture as well as to congestion? This theory is capable of explaining why the length of time spent in a condensed atmosphere should be of such moment, for saturation of the blood will only take place more or less gradually. We can also see why higher pressures are more dangerous than low ones if we admit the operation of Dalton's law in these cases. It also explains why the symptoms are never observed so long as one remains in the pressure, but only after exit. Furthermore, I am satisfied in my own mind that this theory affords a reasonable and scientific explanation as to why an increase in the carbonic acid gas should bring about an increase in the amount of illness and also why, with an atmosphere containing 0·06 per cent. carbonic acid gas at the Baker-street and Waterloo railway tunnel, we had no cases occurring under a three hours' sojourn in the pressure. When we consider the relative solubility of oxygen, nitrogen, and carbonic acid gas, it is within the bounds of probability that the latter is the one dissolved in greatest amount in the blood, though present in such a small quantity in comparison with the other component gases of the atmosphere The application of the law of Dalton explains why pressure, length of stay in that pressure, and amount of carbonic acid gas present should be so intimately connected one with another that it is impossible to consider one without the others. It is true that Bert in analysing the bubbles of air obtained in his experiments on animals found them to consist chiefly of nitrogen. But as Demarquay, quoted by Dr. Snell, has shown, free gases existing in the tissues of the body are absorbed at different rates, and while carbonic acid gas is absorbed in 45 minutes nitrogen may be discovered after several weeks. Is it not possible that the length of time intervening between death and necropsy in Bert's experiments may have been sufficient for the disappearance of the carbonic acid gas? This theory also enables us to comprehend why rapid re-compression followed by a long "locking-out" are in a large majority of cases curative in all forms of the illness, the air being re-absorbed and the gradual "locking-out" enabling it to escape through the lungs. It also accounts for the fact that the sooner re-compression is practised after the onset of the symptoms the more satisfactory are its results.

MORBID ANATOMY.

There having been no fatal cases at the Baker-street and Waterloo railway tunnel works I have had no opportunity of seeing for myself the post-mortem conditions present. There have been a fair number of necropsies following death resulting from compressed air, but many of them seem to have been incompletely performed. Congestion of various organs has usually been present and, in some cases there has been effusion beneath the arachnoid and blood-clots under the dura mater of the cord. Dr. Smith details one of his cases in which Dr. Janeway of New York performed the necropsy. Death had taken place suddenly within two hours of exit. Nothing abnormal was found except congestion of the lungs. It is not stated whether the cavities of the heart were examined for free air bubbles. The spinal canal was not opened. So far the post-mortem examinations made in this condition are not absolutely reliable, for they seem to have been conducted, as far as can be made out, without the precautions necessary for the discovery of free air in the tissues and vessels. The experiments of Bert on animals seem to have been followed by much closer post-mortem investigations.

REMOTE EFFECTS OF WORK IN COMPRESSED AIR.

Does the human organism suffer any ill-effects which may be described as chronic as a result of being subjected to the action of compressed air? I can only say that I have never been able to discover anything which would lead me to answer this question in the affirmative. Many of the men who came before me had worked on and off in compressed air for periods of five, six, and seven years, yet I was unable to find any pathological condition in their organs or arterial systems except in one case—viz., that of a man, 42 years of age, who had worked for varying periods during the last seven years in compressed air and who showed marked arterio-sclerosis apart from any cardiac or renal condition which could be discovered. This sclerosis may have been caused by his occupation, but it is impossible to say definitely that it was.

Regarding the paleness of the face and the general unhealthy appearance of compressed-air workers insisted on by Dr. Smith, I may say that I was not able to detect a greater degree of pallor in these men than was present in men working in other parts of the tunnel, where compressed air was not used, and which is found in most men working underground. Dr. Snell says in this connexion that at the Blackwall Tunnel as ventilation improved the pallor became less marked, so that eventually he could not pick out an air-pressure man by his complexion though previously he had been able to do so

TREATMENT.

In the great majority of cases only one treatment is necessary and that is re-compression. For this purpose we had a medical air lock erected on the stage consisting of a boiler placed horizontally. At one end was a door which was air-tight when closed, and the interior was fitted with bunks, lighted by electricity and heated by steam. A small window and speaking-tubes completed the arrangement. It was connected with the air-compressors and was fitted with a pressure gauge and the necessary taps. The sooner re-compression is practised after the symptoms appear the better as a rule are the results. If a long period has elapsed, even though the pain may be benefited, there is always in joint cases marked stiffness remaining, the condition then being not an acute one but simply the result of the bruising and stretching undergone by the tissues.

The amount of pressure needed for relief depends more on the severity of the case than on the original pressure which produced the symptoms. Persons attacked after coming out of 30 pounds per square inch pressure may feel perfectly relieved when the pressure in the medical lock amounts to 18 pounds, others may require to be re-compressed up to 25 pounds, although the pressure they came out of was only 23 or 24 pounds per square inch.

Decompression must be slow, and I think that it is of advantage not to reduce the pressure faster than at the rate of one pound in three minutes. In my experience re-compression never fails to stop the pain but there are exceptional cases where it returns shortly after exit. In some of these a second re-compression is effectual, in others it is quite useless, and I have given an example of each class in the appended illustrative cases. If the pain returns it invariably does so in the original situation, and the fact that pain should ever return after re-compression is probably owing to the creation by the first attack of a *locus minoris resistentiæ* which renders the passage of air into the tissues easier than escape by way of the respiratory system. In the cases in which the pain returned I had recourse to morphine given hypodermically. It must be used in fairly large doses, a quarter of a grain not being sufficient to control the pain in any of the three cases in which I used it.

Ergot is highly spoken of by Dr. Smith who considered it superior to morphine in relieving the pain. I never found it to be of any benefit except in one variety of case—that in which giddiness and headache are the symptoms. I have used it in doses of from one to two drachms of the fluid extract in cases of this kind and always with the greatest benefit.

In the acute cases it is my experience that liniments are practically useless and the same is true of bandaging.

In the cases of stiffness following the acute symptoms I have used the liniment containing aconite and belladonna recommended by Dr. Snell with the greatest benefit.

ILLUSTRATIVE CASES.

CASE 2.—The patient was a strong and healthy man, aged 26 years, who had been working in the Baker-street and Waterloo railway tunnel works for six days. He had finished an eight-hour "shift" at 6 A.M. on May 29th, and three hours later he had very severe pain in his left hip and thigh. He returned to the works at 8.15 P.M. when I saw him. The pain was then very severe, the left thigh being much swollen, and he could only walk with great difficulty. He was put into the medical lock and the pressure was raised to 18 pounds, at which point the pain had practically gone. The pressure was reduced to normal in 45 minutes and he came out feeling quite well but with much stiffness in the limb. There was still considerable swelling, so the thigh was firmly bandaged and he was given a liniment. When seen on the night of May 30th he stated that he felt quite well and that there was no return of the pain.

CASE 3.—The patient in this case was a man, aged 40 years, who had had previous experience in compressed air. He was a strong, healthy man. He came out of the pressure at 6 A.M. on June 14th, after the regular eight hour "shift," the pressure then being 28 pounds. At about 8.30 A.M. he was seized with pains in his left knee and in his right shoulder and elbow. He returned to the stage at 2 30 P.M. and I re-compressed him up to 25 pounds, the "locking-out" occupying 50 minutes. The pains before going into the lock were most intense, but on coming out the shoulder and elbow were perfectly well, the knee being slightly stiff. There was no return and he went on his "shift" at 10 P.M.

CASE 4.—The patient, a man aged 23 years, had worked in compressed air at Glasgow and had been at the Baker-street and Waterloo railway tunnel works for over a month. He had never been affected before. He came off his "shift" at 6 A.M. and immediately on leaving the lock he was seized with most acute pain in his left arm between the shoulder and elbow. He went back into the pressure and obtained instant relief, but on coming out again the pain returned as severely as before. I was sent for at 9.15 A.M when I found him in great pain. The left upper arm was much swollen and on palpation it gave a crepitant sensation to the examining fingers. He was put in the medical lock and re-compressed up to 22 pounds, coming out in 50 minutes The pain returned but not so severely as at first. I then rubbed his arm with a liniment containing aconite and belladonna and applied a moderately tight bandage without the slightest relief. He was therefore again re-compressed up to 12 pounds, at which point the pain had gone. The "locking-out" took 30 minutes. There was no return of the pain after this second re-compression. The crepitant sensation imparted to the fingers in examining the arm in this case would lead one to suppose that it may possibly have been due to free air in the tissues. Dr. Snell had a similar case occurring in the thigh.

CASE 5.—The patient was a healthy man of small build, aged 26 years, who had had no previous experience in compressed air. He "came off" at 6 A.M on Oct. 12th, after doing his first "shift," and within ten minutes he experienced most intense pain in both knees. He returned at once to the stage and I saw him a few minutes later, and he was then crying and groaning and apparently suffering very greatly. There was no swelling of the joints themselves, but there was a considerable amount of swelling in the muscles of the thighs. He was put into the medical lock and was re compressed up to 22 pounds, at which pressure the pain completely went. The pressure was reduced to normal in one and a half hours, and the pain at once returned. He was then given one and a half drachms of the fluid extract of ergot and was re-compressed to 22 pounds, two hours being occupied in "locking-out." The pain immediately returned and was so intense that I injected a quarter of a grain of sulphate of morphia hypodermically and had to repeat it in half an hour. This controlled the pain and the patient slept till 7 P.M., going home soon afterwards free from pain but hardly able to walk on account of the stiffness of his knee-joints.

CASE 6.—In this case a strong, healthy, spare man, aged 43 years, who had had no previous experience in compressed air, came out of the pressure at 6 P.M. on Oct. 10th after being in for four hours and about an hour later he was seized with most severe pain in the abdomen, the knees, the shoulder, and the elbows. The abdominal pains were most excrutiating and were accompanied by severe and intractable vomiting. He had two physicians at his own home, who on failing to relieve him advised him to come back to the works. He was brought back in a cab about 4.30 A.M. on Oct. 11th, and I saw him about 15 minutes later. He was in great agony, groaning and writhing with pain, and had to be lifted into the medical lock. During re-compression the abdominal pain increased and was so intense that he rolled on the floor of the lock, but when the gauge showed 24 pounds pressure the pain almost completely left him. The pressure was reduced to normal in 80 minutes, and when he came out of the lock he was quite free from abdominal pains and the only joint which was still somewhat painful was the left shoulder. In a short time he was able to proceed home When seen on Oct. 12th the patient said that he felt quite well except for stiffness in the left shoulder. He was advised not to resume work in the air pressure.

CASE 7.—This patient came out of the pressure at 7 P.M. on August 20th, having been in just over three hours, the pressure being about 28 pounds. Almost at once he was seized with the most intense pain in "the small of the back on each side of the spine." It rendered him helpless an made him feel sick. I saw him at 7.15 P.M. and he wa re-compressed, the pain having vanished by the time pressure of 15 pounds was reached. Decompression occupie 65 minutes and he was perfectly well on leaving the loc When seen on the morning of the next day he stated tha he felt perfectly well. There was no return of the pain.

CASE 8.—The patient was a strong healthy man, aged 2 years. He had had previous experience in compressed a and had worked at the Baker-street and Waterloo railwa tunnel works from the commencement. He came out the pressure at 6 A.M. on Oct. 16th after working for eigh hours and an hour later he felt very giddy and began t vomit very violently. There was no pain in the head or els where. He was quite unable to stand. This condition continued for two days and on the third day he began t improve. On Oct 22nd he returned to the works and I sa him for the first time. He was still somewhat giddy, so gave him one and a half drachms of the fluid extract of ergo and in an hour he said that his head was quite clear. At n time was there any loss of power anywhere, the helplessnes being due altogether to the giddiness. The vomiting wa severe and intractable.

CASE 9.—The patient, who was a healthy spare man, age 45 years, had been working in compressed air on and of for the last six years. He had never been affected b it in any way. He had been working at these work since the commencement of operations without having ha any trouble. He came out of the pressure at 10 P.M. o Oct. 13th, and 15 minutes later he had very severe pai in the lower lumbar region on the right side of the spin and pain of a less marked character on the left side. H also had abdominal pains of moderate intensity. He returne at once to the stage, his lower limbs by this time bein completely useless and sensation being much impaired a high up as the iliac crests. I was not sent for, some of his fellow workmen taking it upon themselves to re-compres him, and at a pressure of 18 pounds all trouble had disappeared and he could use his lower limbs as well as ever. But they reduced the pressure to normal in less than ten minutes and, as was to be expected, the pains in his back and the paresis of the lower limbs returned just as he reached home. On Oct. 14th the lumbar pain had disappeared, but power in his legs was still absent and he had also lost power over his bladder and rectum, a catheter and enemas being necessary. He was brought to the stage on Oct. 15th and I saw him when I obtained the information which I have given above. He was then quite unable to move his right leg and could only just move the left leg. Sensation was impaired, but not completely gone, as high as the iliac crests in front and behind. I had little hope of re-compression or of ergot being of use, the interval having been so long, but I thought it well to try them. He was given one drachm of ergot and was re-compressed up to 25 pounds, the pressure being reduced to normal in an hour and three-quarters. There was no improvement at the time, but an hour later he was able to lift both legs and he said that he did not feel so helpless. Having given him instructions regarding himself he wa taken home shortly afterwards. He improved daily and within a week was able to move about on his legs, but the use of a catheter was still necessary. I last saw him o Nov. 9th. He could then walk fairly well and sensation wa much improved, but it was not yet normal and a cathete was still necessary. In this case I believe recovery will b complete, though it may be several months before the ma is able to engage in his ordinary work. As a rule, in these cases the bladder is the last to recover, and the use of catheter may be necessary for a considerable time after the limbs have completely recovered.

The pathology of these cases of paraplegia in which ther is recovery can be reasonably explained by the pressure o air bubbles either in or outside the vessels upon the nervou centres in the cord. It is not probable that where recover takes place there has been rupture of the vessels and consequent hæmorrhrge, though in those cases in which there no recovery but in which the patients remain paraplegic would appear that this is what happens. In the foregoin case the pressure on the cord was certainly not due hæmorrhage because the man was at once completely cure by re-compression, and had the "locking-out" occupied a hour instead of less than ten minutes I am perfectly satisfie that there would have been no return of the paraplegia When I saw the man nearly 48 hours had elapsed, and h was probably then suffering not so much from the pressure as from the results of that pressure on the nervous structures of the cord, but from the fact that the second re-compression was of some benefit there was probably some free air even at that time.

INTERESTING SURGICAL CASES.

BY E. PAGET THURSTAN, M.D., B.A. CANTAB.

THE following is a report of 24 interesting surgical cases which occurred in the practice of Dr. E. J. A. Haynes and myself in Perth, Western Australia. The cases were operated upon by Dr. Haynes. We have thought that a brief account would be interesting to your European readers.

CASE 1. *Left ovarian cyst; ovariotomy.*—The patient was a woman, aged 21 years, who had been under treatment by a medical man for menorrhagia for some time. When Dr. Haynes was called in he found a large tumour which upon examination under chloroform proved to be a left ovarian cyst. The uterus was also enlarged to four inches. The peculiarity in this case was the severe menorrhagia—indeed, metrorrhagia—which pointed to uterine rather than to ovarian trouble. The patient was removed to a private hospital and Dr. Haynes performed ovariotomy in the usual way. The cyst was of the size of a man's head. The patient made an uninterrupted recovery notwithstanding that she was blanched by the severe hæmorrhage prior to coming under our care.

CASE 2. *Carcinoma of the liver.*—The patient was a man, aged 48 years. An exploratory incision was made, when a soft fluctuating tumour of about the size of an orange was found over the right lobe of the liver just below the point of the ninth rib. The liver was much enlarged, but was smooth and even. The patient fancied that the side had been swollen for 12 months before. Undoubtedly during the past three months it had been increasing in size and becoming painful. He had lived for years in South Australia, where hydatids are common, and he had also suffered from dysentery on the goldfields a few months before. There seemed to be no symptoms—e.g., wasting or jaundice—pointing to carcinoma. The diagnosis apparently lay between hydatids and liver abscess. A vertical incision was made three inches in length along the outer edge of the rectus and immediately on opening the peritoneum the case showed itself to be one of carcinoma of the liver. Subsequently there was no vomiting or abnormal temperature. After the third day the patient refused to keep his bed and on the fourth he left the hospital despite all our persuasions. Subsequently we learned that he recovered completely from the operation, but died a few months later in Fremantle from the malignant disease.

CASE 3. *Extra-uterine fœtation; laparotomy.*—In this case (of my partner, Dr. Haynes) extra-uterine fœtation was diagnosed, but the patient, a married woman, was so collapsed from constant vomiting, &c., that it was deemed advisable to postpone the operation, if possible, for a few days to endeavour to restore her strength. For a week she was kept in bed and was fed per rectum and she distinctly rallied. An incision four inches in length was made in the median line below the umbilicus. On opening the peritoneum a tumour of the size of a large orange was visible, but the uterus was bound down, the bowels and omentum were adherent in a mass over the tumour, and the relation of the several parts to one another was completely distorted. It being impossible to tie off the sac Kelly's suggestion was followed, and sharp-pointed scissors were thrust from the vagina into the sac and an indiarubber tube was inserted. The abdomen was then closed. For three days all went well, the discharge coming freely through the vagina. Then symptoms of heart failure set in, and, despite hypodermic injections of strychnine and rectal injections of brandy, the patient rapidly collapsed and died in eight hours from the onset of the symptoms.

CASE 4. *Perinephritic abscess; abdominal section.*—The patient was a married woman, aged 42 years. She had had no family. She had been in the public hospital, but had been discharged on the ground that there was nothing the matter with her. On examination there was found to be pain on pressure over the region of the ascending colon. On very deep pressure there was a feeling of a tense fluctuating tumour in the direction of a vertical line from the point of the tenth rib to the level of the umbilicus. The patient had been feverish for some weeks before coming under our care. An incision was made from the tip of the tenth rib downwards and forwards for four inches, the peritoneum was opened, the liver was pulled up, and the flexure of the colon was drawn inwards. A tense tumour with a dense white covering could be seen which could be traced up under the liver and down to the level of the umbilicus. There was considerable matting together of adjacent parts, which made it doubtful whether the mass was a localised psoas abscess or a perinephritic abscess. The parietal peritoneum was with much difficulty stitched down to the sac and the tumour was then aspirated. About one and a half pints of offensive bluish pus were evacuated. An incision was then made, a large rubber tube was inserted, and the space around was packed with iodoform gauze. The gauze and tube were brought through the middle of the abdominal wound and the rest of the wound was stitched up. When the gauze covering was removed it was found that there was a free discharge through the tube. The wound was thereafter daily dressed with iodoform gauze. From the sixth day onwards the cavity was syringed out with weak iodine solution and the tube was removed and cleansed daily. The abdominal stitches were removed on the twelfth day, the whole wound being soundly healed except the portion in which was the tube. The patient left the hospital in three weeks and was then well except for the fact that the wound was discharging. This case was done without fee on our part and the cost of her stay in hospital was obtained by charitable subscriptions. This fund being exhausted she had no opportunity of returning or of undergoing further operation which was indicated. She was seen from time to time for a few weeks, but the wound never completely closed. The cause of this abscess was very obscure. There was no spinal mischief or anything to indicate psoas abscess. The probability seems to be that it was perinephritic.

CASE 5. *Extra-uterine fœtation on the left side; laparotomy.*—The patient was a married woman. The cyst burst during the operation and its thick grumous contents were baled out with a silver-plated ladle. The broad ligament had to be dissected out. Dr. Haynes used the purse string stitch to close the peritoneum as recommended by Dr. O'Hara. The patient made an uninterrupted recovery and she left the hospital in a month, being then well.

CASE 6. *Extra-uterine fœtation on the left side; ani-laparotomy.*—The purse-string stitch was again used. The patient, a married woman, left the hospital in six weeks, after an uninterrupted recovery, and returned to the country. We subsequently heard that at the end of her journey a jollification was held in honour of her return. Coitus was probably indulged in. The medical man who attended her informed us that pelvic cellulitis supervened, to which she succumbed a few months later.

CASE 7. *Hydatids of the brain; trephining.*—The patient, a boy, aged 11 years, had been treated for years by various medical men for severe pains in the head, which were attributed to a fall on the head. For a year or two previously to his coming to Perth for advice he had had epileptiform convulsions. These convulsions were increasing in frequency and the mental condition was deteriorating rapidly. There was also motor paralysis on the right side for some days after each fit. Dr. Haynes diagnosed cerebral tumour of the left motor region. At the operation, as soon as the trephine circle (made over the region of the fissure of Rolando) was enlarged, the dura mater bulged into the wound. When it was incised nearly half a pint of hydatid fluid and daughter cysts escaped. Another sac was detected towards the right frontal eminence. A second trephine hole was cut in this spot. The bone was much thinned, being in one spot scarcely thicker than an eggshell. The dura mater bulged into the wound as before and four ounces of hydatid fluid and daughter cysts were removed. It was found that a probe would pass from one sac to the other, the pressure of the sac in the left hemisphere having apparently absorbed the falciform process of the dura mater. The sac was subdural, the surface of the dura mater being lined by the wall of the sac. The wall was thin and adherent and the cyst could not, therefore, be shelled out. Just prior to the operation the lad had had several fits followed by a semi-conscious condition from which he could be roused, but he invariably used one of three phrases: "Shut up," "Hurry up," and "Don't." For a few days after the operation the patient improved in intelligence and in motor power. Hydatids kept coming away in numbers and it was evident that the brain was extensively permeated with cysts. He died within three months of the operation. It is possible that had the diagnosis been made years previously the lad might have recovered health as he rallied well from the operation. It is noticeable that he knew when the fits were coming on and used to run to his mother crying, "Oh, mammy, save me!" His head appeared large for a boy of his age.

CASE 8. *Double pyosalpynx; abdominal section.*—The patient was a married woman. Both tubes were greatly distended with pus and had to be removed, and the left tube was slightly ruptured during its removal. The abdomen was thoroughly flushed out with normal saline solution at a temperature of 110° F. The peritoneum was closed by purse-stitch. No drain was left in. This probably was the turning point in the operation, as the abdominal wound broke down without causing any symptoms of peritonitis. The external wound had been soiled by the ruptured tube and possibly had been rather bruised during the strong retraction of the incision which was necessary for removal of such large tubes. A very considerable quantity of pus was discharged daily from the abdominal wound. Almost every lotion recommended in the text-books was tried without success in the endeavour to check this formation of pus, until Kelly's advice was followed and a hydrogen peroxide 5 per cent. solution and a 0·5 per cent. formalin solution were used, when rapid improvement took place. A collection of pus formed in Douglas's pouch, whether from the remains of infection in the stump of the tubes or from cellulitis it was hard to say. This was incised per vaginam and drained and was ultimately completely closed. The abdominal wound healed at the end of three weeks. The patient made a perfect recovery and has since been actively managing a business without needing to lie up for a day. The complication of the suppuration burrowing under the recti and spreading between the planes of the abdominal muscles is distinctly one to be dreaded, and the value of syringing with peroxide and formalin is well worth remembering.

CASE 9. *Tuberculous kidney; removal of the left kidney.*—Medical treatment having failed to give relief to the patient (a man) it was decided to remove the left kidney, which was subsequently found to be very large, weighing over three ounces, and to contain abscesses. At the operation the incision was made anteriorly, as recommended by Mr. Harrison Cripps. Though easier of performance than with the posterior incision there is the drawback that the peritoneal cavity is opened. When there is purulent infection in the kidney, as in this case, the peritoneum can hardly fail to become affected, and this occurred in the present instance. The patient ultimately succumbed to peritonitis, and Dr. Haynes attributes his want of success to his doing the operation intra-peritoneally instead of extra-peritoneally.

CASE 10. *Hydatids of the abdomen; abdominal section.*—In this case, that of a married woman, there was a well-defined tumour running across the right epigastrium, and apparently across the liver, as the area of liver dulness was much increased downwards Fluctuation could be made out. The patient was a young woman, only 23 years of age. The diagnosis was hydatids. An incision three inches long was made over the right rectus. After the fibres of the muscle had been separated it was found that the cavity of the peritoneum had become shut off and there was nothing below the muscle but the adventitious sac of the tumour. On aspiration a gallon of clean hydatid fluid was drawn off. After incision the sac was kept open by fixation forceps and the mother cyst, though very thin-walled, was safely removed without rupture. It proved to be an acephalous hydatid cyst. Further exploration showed that the cyst had pushed the liver down some three inches and quite a cavity existed between the wall of the cyst and the diaphragm. The cyst was sutured with catgut and the abdominal wall was closed by interrupted silkworm sutures. The patient made an uninterrupted recovery and left the hospital three weeks after the operation.

CASE 11. *Uterine fibroids; double oophorectomy.*—On opening the abdomen of this patient, a married woman, a very formidable array of complications was made manifest. There were three fibroids attached to the fundus; the posterior portion of the uterus was adherent to the pelvis; one of the fibroids had dissected up the right broad ligament, and both broad ligaments were twisted round the womb and flattened out. Apparently the only choice lay between hysterectomy and removal of the ovaries. The patient was in a very low condition from previous hæmorrhages and the larger operation seemed contra-indicated, so both ovaries were removed. Dr. Haynes found this somewhat difficult owing to the twisting of the ligaments. The patient made an uninterrupted recovery. Her symptoms have abated and at the time of writing she is perfectly well.

CASE 12. *Appendicitis; abdominal section.*—The patient was a married woman, aged 40 years. When I first saw her she had great pain over McBurney's point, with tenderness, rigors, and a temperature indicating suppuration. An incision three and a half inches long was made over the site of prominence in the direction of the fibres of the external oblique, as recommended by Greig Smith. The muscular tissues of this and the internal oblique were separated rather than cut and a free incision was made through the transversalis. Below this all the parts were so matted together that it was difficult to recognise the structures. At this stage the peritoneal cavity was inadvertently opened, but was easily stitched up again with a continuous catgut suture. The dissection was then continued down to the cæcum, the abscess was discovered, and fully an ounce of pus was evacuated. The appendix could be made out in the abscess cavity, but Dr. Haynes decided not to attempt its removal. An iodoform gauze drain was inserted, the several muscular layers were sutured with No. 3 silk and the skin with silkworm gut, two deep silkworm gut sutures being also inserted on each side of the drain. The fever, vomiting, and bowel obstruction were at once relieved. On the day after the operation the gauze was removed and a rubber tube was inserted. It was some time before the sinus finally closed, but the patient made an excellent recovery and remains in splendid health.

CASE 13. *Strangulation by Meckel's diverticulum; abdominal section.*—The patient (a man) had been treated on the goldfields for appendicitis, which his symptoms closely resembled, and it is doubtful whether so unusual a course of obstruction would have been diagnosed anywhere. A tumour could be felt on a level with the umbilicus and to the right of it. There were symptoms of obstruction, and the trouble having lasted some time an exploratory incision, with the option of performing any further operation indicated at the time, seemed to be the right course. A median incision was made and ultimately extended to four inches in length from below the umbilicus towards the symphysis pubis. A mass of the size of a man's fist, matted over with omentum, was drawn out of the wound. The mass consisted of the small bowel covered by omentum strongly adherent to the ascending colon. The ragged uneven omentum was dissected off the mass and ligatured with fine silk and removed. As the separation of the several parts of the mass continued it was found that two coils of the ileum, doubled on themselves, were adherent to the colon. With extreme care Dr. Haynes dissected these apart, having to tie several bleeding points, which was done with fine silk. Then for the first time the cause of all the trouble was discovered—Meckel's diverticulum had remained patent. It was as thick as a little finger, about two and a half inches long; it was club-shaped, and it sprang from the ileum six inches from its termination in the colon. It was firmly adherent to the two coils of ileum, from which it was dissected with extreme difficulty. There was sharp bleeding from the separated walls of the small bowel, which was stopped by passing a straw needle armed with fine silk beneath the bleeding point. The diverticulum was clamped close to the ileum, was cut off, and was secured by over-stitching, and was then inverted into the lumen of the gut, the peritoneal coats of which were brought together with fine silk, just as in removal of the appendix. The patient made a complete recovery.

CASE 14. *Ovarian cyst; ovariotomy.*—The patient, a married woman, had an ovarian tumour which was removed in the usual way. There was nothing in the operation deserving record. During the three days succeeding the operation everything progressed most favourably and she seemed to be out of danger. On the third night she was suddenly seized with acute pain in the chest; she gasped for breath, threw her hands about wildly, and begged the nurse to open the window as she was "smothering." She died before Dr. Haynes could get to her. No post-mortem examination was obtained, but there was little doubt that the cause of death was pulmonary embolism.

CASE 15. *Stone in the kidney; nephrotomy of the right side.*—The patient was a male. The case presented all the symptoms of stone in the kidney. After consultation an operation was determined on. Dr. Haynes made the usual lumbar incision and found the kidney quite easily. It was much enlarged and was bound down by old peri-nephritic adhesions. Great difficulty was experienced in separating the kidney and in bringing it out of the wound. After several exploratory punctures a soft friable mass was located towards the lower edge. This was incised and was thoroughly washed out. The kidney was returned and the external wound brought together with deep silkworm sutures. A drainage tube was left in for four days, being withdrawn gradually. The patient made a very good recovery and left the hospital in splendid health.

CASE 16. *Hystero-epilepsy; double oophorectomy.*—The patient, a married woman, had had two children, the last born eight years previously. She had had constant epileptiform seizures. During the periods these were exceptionally severe and frequent and they left her drowsy and helpless. Almost every medicine in the British Pharmacopœia had been tried without avail and insanity was feared. Bimanual examination disclosed both ovaries to be enlarged and painful, and pressure was sufficient to provoke a seizure. It was resolved to remove both ovaries and this was done. The left ovary proved to be markedly cystic and the right ovary was also cystic but in a less degree The patient made a good recovery with immediate improvement. She has since continued to improve and the fits have ceased.

CASE 17. *Large uterine fibroid; double oophorectomy.*—This patient, a married woman, was practically slowly bleeding to death when she came to us. On examination an enormous fibroid was made out. Abdominal section showed that the tumour was sessile and attached to the fundus uteri. Removal of the tumour was impossible, and both ovaries were therefore removed. The patient made an uninterrupted recovery, and when she was last heard of the hæmorrhage had ceased, the tumour had shrunk to half its former dimensions, and she was able to attend to her domestic duties instead of being a confirmed invalid.

CASE 18. *Advanced cancer of the cervix uteri; removal impossible; blood supply tied off.*—This patient, a married woman, was in a deplorable condition, being almost at death's door from exhaustion and hæmorrhage. She had travelled for 600 miles by land and sea from a distant goldfield to Perth for medical treatment. She entered the Public Hospital, but she was told that her case was too far advanced for operative treatment. With this view Dr. Haynes coincided, so far as removal was concerned, for the disease had spread from the cervix and had implicated the vault of the vagina The uterus generally was much enlarged. The patient was 50 years of age and the symptoms had first shown themselves six months previously. About this time Dr. Haynes noticed that the medical journals were giving accounts of Dr. Jannesco's treatment of inoperable cases by cutting off the blood-supply, and he determined to follow Dr. Jannesco's instructions in the case. It was represented to the family that such an operation would not cure the disease, but that it would, if successful, considerably prolong life and would greatly mitigate the present urgency of the symptoms Consent to the operation was eagerly given. A median incision was made four inches in length below the umbilicus. The bowels were held back and a good view of both broad ligaments was obtained. The ovarian arteries on both sides were tied off with No. 3 silk twist, as were both round ligaments with their arteries. Then a long right-angled needle was passed, first on one side and then on the other, close to the uterus, low down near the insertion into the vagina, and the arteries of the uterus were there tied. Despite the low condition of the patient uninterrupted recovery took place from the laparotomy. During her stay in hospital the ulcerated surface was curetted and treated every third day with an application of iodised phenol and glycerine tampons, and the vagina was daily syringed with permanganate solution. By the time she left the hæmorrhage and foul discharge had ceased and her health was greatly improved. She was able to travel back by rail and to resume her business and to continue it for six months until she was able to dispose of the goodwill. The disease, of course, has spread, but it is now nearly 12 months since the operation and the patient is still able to get about. Dr. Haynes considers this operation as a striking proof of the wisdom of Dr Jannesco's mode of procedure, as under no other known treatment would the poor woman have been alive to-day.

CASE 19 *Cystic ovary; left oophorectomy*—The prominent symptoms in this case, in which the patient was a married woman, were extreme irritability of the bladder and pain in the left side and the left leg which became intolerable for a week during each menstrual period and which was accompanied by constant vomiting. Laparotomy was performed The left ovary, which was found to be as big as a mandarin orange, was removed. Recovery was uninterrupted and complete relief from all the symptoms was secured.

CASE 20. *Internal strangulation in the ileo cæcal fossa; laparotomy.*—The patient, a boy, three and a half years of age, had been under treatment at the Public Hospital for nine months for worms. When brought to Dr. Haynes he had a tumour of the size and shape of an ounce medicine bottle about an inch above McBurney's point. The chief symptoms were pains in the abdomen accompanied by vomiting and terminating in convulsive seizures. Operation was determined upon, but the child was in such a low condition that it was deemed advisable to feed him per rectum for three days first. An incision two inches in length was made in the median line. Nothing was found wrong with the cæcum or with the appendix. A loop of ileum four inches in length had passed through an aperture into the ileo-cæcal fossa and passed upwards under the colon towards the left kidney. Very great difficulty was experienced in withdrawing the bowel, which was much congested. In the coats of the ileum at the bend was a lump of about half the size of a walnut, probably inflammatory, thickest at the spot where the bowel was first nipped. An uninterrupted recovery and a perfect cure of the symptoms ensued. According to Maylard and Treves this is a very rare form of strangulation and possibly is the first recorded in the living subject. There was no mistake about the case, however, as Dr. Haynes took great pains to verify the relation of the parts. Three lengths of ileum appeared in view at first. It was found that the lowest one was the part normally joining the cæcum, the two upper coils being the strangulated parts. The ileo-cæcal fold covering the fossa was well defined, and on the finger being inserted subsequently the direction of the sac under the colon could distinctly be made out.

CASE 21. *Adhesions subsequently to former ovariotomy; laparotomy and separation of the adhesions.*—This patient, a married woman, aged 32 years, had had her right ovary removed in Melbourne 10 years previously. The recovery had been very slow and a sinus remained for 18 months. She had ever since been a martyr to pain and the greatest difficulty had always been experienced in obtaining relief of the bowels; indeed, at times the trouble amounted to obstruction. On opening the abdomen it was difficult to define the peritoneal cavity at all. The small intestine was adherent to the old abdominal incision, to the uterus (which was retroverted and firmly bound down), and also to the large bowel. The omentum could not be defined. How a human being could have lived with her intestines in such a tangle was a mystery. Great difficulty was experienced in separating the adhesions and tying the bleeding points. The left ovary proved healthy, and it was therefore not interfered with. The uterus was freed and replaced in position. Recovery was uninterrupted Two months later, at a subsequent operation, Dr. Haynes removed several large piles with the benzine cautery. Since then there has been no trouble with the bowels and the patient enjoys as good health as she did prior to her marriage twelve years before.

CASE 22. *Traumatic ovaritis on the left side; oophorectomy.*—This patient, a married woman, aged 38 years, had received a kick from a horse nine months before. She was drifting into permanent invalidism through abdominal pain and irritability of the bladder, the symptoms being very intense at the menstrual epochs. The ovary proved to be large and cystic. A cicatrix ran transversely across the outer third of it, the tube was thickened, and the broad ligament showed signs of old inflammatory trouble. The left ovarian vein was enlarged and varicose, this condition being probably caused by the kick. The patient made an uneventful recovery.

CASE 23. *Hydatid of the liver: abdominal section.*—This case, in which the patient was a married woman, has been already reported.[1] Dr Haynes had previously removed five large hydatids from the abdomen. In the former account of the case it was mentioned that the patient was three months pregnant at the time of operation. Two months later she returned, complaining of trouble in the vagina Dr. Haynes then removed per vaginam a cyst containing six ounces of hydatid fluid and daughter cysts. The pregnancy continued to seven and a half months, when labour set in and she was delivered of a living child, but the infant died in a few days. On the present occasion the patient presented a large tumour reaching close up to the ribs above and extending from the right nipple-line to two inches beyond the median line. A vertical incision three and a half inches long was made over the prominent part of the tumour. The sac wall was stitched to the peritoneum with chromic gut. The tumour was aspirated and about two quarts of fluid were drawn off. The flow through the needle ended very suddenly, but as no more fluid could be persuaded to pass Dr. Haynes incised the tumour and the wound was kept open by Spencer Wells forceps. The theory was that the mother cyst had slipped off the point of the needle at the moment that the flow ceased, and the correctness of this was proved eight days after the operation when in the course of the usual syringing the mother cyst presented in the wound and was successfully removed. The adventitious sac was stitched to the abdominal incision by silk twist, the needle taking up the peritoneum and passing through the whole thickness of the abdominal wall. The remainder of the incision was closed with silkworm gut. Following Mr. Treves's advice Dr. Haynes inserted a very large rubber drain and dressed the wound with iodoform gauze and wood-wool. Iodine solution was used for the daily syringing. The large tube was left in for 10 days, being gradually shortened, then a smaller tube was inserted, and finally a smaller one still until the wound closed. This cyst was acephalous and had no daughter cysts, and this was the case also with two others, the remaining four having subsidiary cysts The paralysis of the left arm from which the patient suffered after the first operation had entirely disappeared.

---

[1] THE LANCET, April 29th, 1899, p 1141.

CASE 24 *Traumatic varicose aneurysm of the thigh; ligature of the vein and the artery.*—The patient, a young man, aged 25 years, was cutting a side of bacon with a long pointed butcher's knife when it slipped and entered his thigh an inch and a half below Poupart's ligament and half an inch to the outer side of the course of the femoral artery. He was under treatment on the goldfields and five months had elapsed from the receipt of the injury, three of which he spent in bed, before he consulted Dr. Haynes. A tumour was visible just below the fold of the groin three and a half inches in its long diameter, with its summit elevated half an inch. There were visible pulsation and a distinct thrill in the tumour. A loud, booming bruit was heard over the elevated area, downwards for two inches along the course of the femoral and profunda arteries and upwards along the external iliac artery. Pressure on this artery caused cessation of thrill and bruit below. Signorini's tourniquet was applied over a Barnes's uterine-dilating bag filled with water and kept on for 18 hours. Thrill, bruit, and pulsation all disappeared during treatment but re-appeared immediately it was left off. The risks in ligaturing the iliac and common femorals being so great Dr. Haynes preferred to cut down over the seat of injury with a view to finding and tying the injured vessels and turning out the clots if necessary. A three-inch incision was made over the course of the femoral artery, starting just below Poupart's ligament. As soon as the sheath of that vessel was defined the tumour was found to run along its outer side and apparently to pass underneath it lower down. Accordingly the incision was prolonged and the dissection carried further down The sac of the aneurysm was defined close to the outer side of the profunda. The external circumflex seemed to be imbedded in the infiltrated tissue of the sac, but the integrity of the coats of the profunda and superficial femoral was clear. The thrill could be felt under and to the outer side of these vessels. The tissues were much matted together and the branches of the anterior crural nerve were defined with difficulty. The external circumflex was ligatured (after the sartorius had been dissected free and drawn outwards) about an inch from the profunda The thrill and pulsation at once ceased. Just above the artery was a dilated vein of about the size of a No. 6 catheter, which seemed to come from the aneurysmal sac. In endeavouring to ligature this the sac, being very thin, burst at that part. For the moment the hæmorrhage was rather alarming, but it was stopped by sponge-pressure and the vein was successfully tied. This vein was apparently one of the venæ comites, though separated by half an inch from the artery. The incision was closed by silkworm gut, a few strands of silk being inserted as a drain. The dressing was iodoform gauze and sublimate wool The whole limb was bandaged and an outside splint was applied from the axilla to the ankle. The drain was removed at the end of a week. The patient made an excellent recovery. He was ordered to wear an elastic stocking as a support.

Perth, West Australia.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

REMARKS ON A NEW INTESTINAL ASTRINGENT.

By J. PORTER PARKINSON, M.D., M.R.C.P. LOND.,

PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL, AND PHYSICIAN TO OUT-PATIENTS AT THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

IT is well known that tannin, though an energetic astringent when used locally, nevertheless exercises its effects chiefly upon the upper parts of the gastro-intestinal tract, as the mouth and stomach, coagulating the albuminous fluids there and also precipitating the pepsin. On this account it interferes with digestion. It is also rapidly absorbed from these mucous surfaces as gallic acid and then is useless as an astringent; hence, except when it is given in huge doses, it does not reach the lower part of the intestine and so can exert no astringent action there.

Many preparations have been placed upon the market, such as tannigen, tannalbin, and tannoform, all of which are of more value than tannin as intestinal astringents, but all are to a large extent split up in the stomach. In 1899 Dr. Sztankay prepared a derivative of tannin in which it is so combined with albumin and keratin that a minimum of disintegration occurs in the stomach and 72 per cent. of the amount given passes into the intestines, which is nearly twice the amount of any other astringent unchanged in the stomach. To this compound he gave the name of "Honthin." This substance, as now prepared by Messrs. Hell and Co. of Troppau, is a brownish powder, insoluble in water but partly soluble in saline solutions, and is without taste or smell. Its action is a precipitation of albumin and mucus such as are found upon catarrhally inflamed mucous membranes, thus protecting these membranes from further irritation and preventing the penetration of organisms or toxins. It also contracts the superficial vessels and diminishes the secretion of fluid. It has been used by Dr. Kölbl of Vienna with striking results in cases of acute, subacute, and chronic diarrhœa both in children and adults. The average dose for an adult is 20 grains three times a day. It is best given as a powder placed upon the tongue, followed by a drink of milk or water, and as it is tasteless children take it well; it is also absolutely non-toxic and so there is no danger of giving an overdose.

My experience of this drug extends over the past six months, during which time I have repeatedly used it in hospital and private cases with good results. I have used it most frequently in the diarrhœa of children. In these the beneficial effect is seen in the course of a day or two in diminution of the number and increase of solidity of the stools with lessening of the amount of mucus they contain. I have generally commenced treatment by the administration of a single dose of castor oil and have then prescribed doses of between five and ten grains of honthin three times a day for children between the ages of two years and ten years. It is most generally useful in cases of diarrhœa which continue in spite of careful dieting and the administration of the usual remedies; it has but little effect in reducing the offensiveness of such motions though it diminishes their frequency, and it does not appear to be so generally useful in the choleraic form of diarrhœa in which very large quantities of fluid are discharged. In cases of chronic colitis in adults I have used it with marked benefit and it appears to be worthy of trial in cases of acute or chronic dysentery.

I have thought it worth while giving a short account of this drug as it appears to be little known in England, for there was considerable difficulty and delay in procuring it and many of the best known pharmaceutical chemists appeared not even to have heard its name.

Wimpole-street, W.

A CASE OF CHRONIC DILATATION OF THE STOMACH ENDING IN DEATH FROM GENERAL TETANIC CONVULSIONS.

By D. D'ESTERRE, M.D., B.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a man, aged 30 years, who for three years past had suffered from symptoms of dyspepsia occasionally accompanied with vomiting. At one time he was a heavy drinker and a large eater, but he became very careful and abstemious in the matter of food and drink, which even in small quantities caused him pain and uneasiness. There was no palpable tumour within the abdomen. His most troublesome complaint was the vomiting of enormous quantities of coffee-coloured fluid about twice a week. His wife stated that the quantity was sometimes nearly a gallon. He also suffered much from eructation of gas. The physical signs of gastrectasia were present. He was instructed in the use of the stomach-tube, in which he became quite expert, and often expressed himself as feeling much better after its use. However, after a slight improvement he was suddenly attacked with extremely painful convulsions of a tetanic character affecting chiefly the flexor muscles of the arms and hands and in a lesser degree those of the abdomen, legs, head, and neck. Opisthotonos was at one time marked and he also showed the risus sardonicus. This attack was overcome with large doses of chloral hydrate, bromide of potassium, and tincture of opium, and subsequently he was given sulphate of soda and magnesium as well as enemata to counteract the constipation. He improved sufficiently to go about again and resume his work, but he succumbed to a similar seizure a few months later.

Regarding the pathology of these convulsions, which are distinctly rare, it may be summed up as uncertain, but resting at present on three theories: (1) Kussmaul's idea of the sudden decrease of water in the tissues of a subject already very dry, as occurs in cases of cholera; (2) Gerhardt's suggestion that the tetany is due to the absorption of products of decomposition; and (3) Ewald's suggestion that they are a manifestation of reflex action analogous to convulsions in children with worms. If the first theory be correct it would seem advisable to administer large rectal injections or employ transfusion, but similar attacks follow other diseases which cannot be traced to such a cause as dehydration of the tissues. If the second theory be correct tetany would not be expected to occur in cases where the stomach-tube was regularly and thoroughly used as in the case above narrated. The third-mentioned theory of the reflex nature of tetany in these instances can hardly be disproved and gains strength from the well-known cases of increased nervous irritability, mechanical and electrical, which accompanies auto-intoxication.

Gipsy-hill, S.E.

THE PYREXIA OF SYPHILIS.

By P. W. BASSETT-SMITH,
STAFF-SURGEON, R.N.

AT the meeting of the Clinical Society of London held on Nov. 23rd[1] Mr. Campbell Williams brought forward a case of fever which he called "intermittent essential fever" of syphilis, in contra-distinction to the fever frequently found in the early secondary period, and it was then pointed out that this condition was far from uncommon, though there is very little reference to the peculiar characters in the usual text-books. In the article by Mr. Jonathan Hutchinson on the disease, as found in Allbutt's "System of Medicine," it is not mentioned. The diagnosis of these cases is often obscure, as the fever is frequently unattended by any marked specific characters, the patient being quite free from rash, gummata, or other usual manifestations, and the intermittency of the fever often leads to the diagnosis of malaria or tubercle.

In a case lately under treatment in the Royal Naval Hospital, Haslar, the course of the disease was interesting. A man, aged 25 years, had been invalided from the West Indies for fever of an irregular type; he was admitted into Haslar Hospital in January, 1900, and was under treatment for post-influenzal pyrexia, being then very anæmic. He returned to duty for six months, but he was again admitted in August for malaria. Examination of his blood showed no evidence of this, but it was noticed that there was a relatively great increase of lymphocytes, as distinct from the polymorpho-nuclear leucocytes (neutrophiles). On a blood count being made there was seen to be a reduction of the red cells (2,800,000) without nucleated forms, but only a slight total increase of white cells (13,600). This, with the marked anæmia, tendency to epistaxis, and slight enlargement of the glands in the groin, led to the diagnosis of early lymphatic leukæmia. His temperature was remarkable, varying as much as 7° F. at times between night and morning, but without rigors and with scarcely any constitutional symptoms. The patient was treated with arsenic, iron, digitalis, &c., for ten weeks, and for a short time with mercury with chalk. Regular examinations of the blood showed the same characters throughout with an extraordinary abundance of blood-plates, this being beautifully demonstrated by using Louis Jenner's stain. As there was an old history of syphilis he was later put on iodide of potassium and bark, with the result that in three days the temperature fell to normal and never again rose.

This question of treatment is interesting as agreeing with the experience of Dr. T. D. Savill that the iodides gave more favourable results than mercury, for though early in the course of the disease this patient was taking the latter as an anti-specific remedy the temperature did not fall to normal. Cabot[2] states that in certain stages of syphilis there are a decrease in the number of red cells and an increase of lymphocytes as was found in this man, but he does not mention the increase in the blood-plates. The peculiar intermittent fever with such intense oscillations is noticed by Dr. Burney Yeo, and a similar case is reported by Dr Sidney Phillips,[3] in which the pyrexia lasted for months, resembling tertian ague, but yielded at once to iodide of potassium. It is probable that many cases of indefinite fever so common in the services are of this character.

Haslar.

HERNIA STRANGULATED IN THE INGUINAL CANAL; RADICAL CURE.

By J. B. PIKE, M.R.C.S. ENG., L.R.C.P. EDIN.

THE patient, who was a foreman railway porter, aged 35 years, for about a year had noticed a lump in his right groin. On Oct. 16th, 1900, this became larger after exertion, and vomiting and pain very shortly supervened. The hernia was partially reduced the same evening, but some slight fulness was still left in the inguinal region. On seeing the patient the next morning I found vomiting still persisting and a distinct fulness remaining, although the external ring was quite free. On inserting the finger deeply through the ring a small tumour was felt, occupying the canal. The patient was at once removed to the Loughborough Hospital and herniotomy was performed as soon as possible. On opening the sac some very congested bowel was found, which was retained by a tight constriction at the neck of the sac. The stricture having been divided and the intestine returned the sac was found to be much thickened and adherent to the spermatic cord, from which it was only separated with considerable difficulty. This having been done the neck of the sac was transfixed and ligatured with catgut and the sac cut off. A deep silk suture was then passed through the neck of the sac and the edges of the wound, the remainder being brought together with silkworm gut. The after progress of the case was uneventful. There is now (six weeks after the operation) a very slight tendency to bulging in the inguinal region on coughing. As a precaution a light truss is being worn. Primary union was made more probable by the incision lying well above the scrotal tissue.

Loughborough.

A CASE OF POISONING WITH A SMALL DOSE OF CHLORALOSE.

By EDWARD H. DOUTY, M.D. CANTAB.

Professor Bradbury's remarks about chloralose in his Croonian Lectures for 1899 lead me to relate the following case.

I was called at about 12 midnight to a young woman who was supposed to be in a fit. She had gone to bed at 11 P.M. She had been in the habit of indulging in chloral and also in cocaine at home, but she had taken very little while at Davos. A physician in London had given her cachets of chloralose, eight grains in each, to take for sleeplessness. She took one for the first time that night. I found her in great distress, unable to move her legs or her arms, with a feeling of numbness in them, the numbness being more marked on the right side. She could not move. Her mind was clear but her speech was slow. Her pulse was good. She recovered in five or six hours. A week afterwards she took another cachet and I was called at about 1 A.M. by her friend who slept in her room because she would not answer when spoken to and again was thought to be in a fit. She was in a cramped-up posture of emprosthotonos, her thighs were tightly flexed on her abdomen, and her chin was forced down on her chest. Respiration was almost inappreciable and very slow and she was cyanosed. Her pulse was 80 and fairly good. Her extremities were not cold. She was quite unconscious and I could not rouse her. I had difficulty in overcoming the contraction of her limbs and neck, but having done so I performed artificial respiration for half an hour, whilst others applied very hot water to her chest and head, and as soon as she could swallow we forced down some brandy, and her breathing improved, but was very slow. In an hour it was possible to get a grunt in reply to questions. She remained in that state for six hours and was torpid all the next day, then seemed quite herself again. The small extent to which the heart seemed affected on each occasion quite bore out Professor Bradbury's observations in his experiments.

MIDDLESEX HOSPITAL.

A CASE OF PERFORATED GASTRIC ULCER.

(Under the care of Mr. T. H. KELLOCK.)

IN the lectures on the Surgery of the Stomach delivered in March last by Professor Mayo Robson there are given statistics of 429 cases of perforated gastric ulcer treated by operation. Of these 193 patients recovered and 236 died.[1] This is a mortality of 55 per cent. The most important element in prognosis in cases of perforation treated by laparotomy is the length of time which has elapsed before the operation is performed. In the lectures already quoted it is shown that of cases under 12 hours the death-rate was 28 per cent.; from 12 to 24 hours it was 63 per cent.; and from 24 to 36 hours it was 87 per cent. For the notes of the case we are indebted to Mr. R. Ainsworth, house surgeon, and Mr. C. W. Rowntree, dresser.

A single woman, 22 years of age, a domestic servant, was admitted into the Middlesex Hospital at 1 A.M. on Sept. 20th, 1900, suffering from vomiting and pain in the back, shoulders, and abdomen. She stated that for five years she had suffered severe pain after taking food; the pain came on immediately after a meal and was most acute in the epigastrium. She had occasionally vomited about a quarter of an hour after a meal and the pain was then much relieved; on one or two occasions there had been a little blood in the vomited material. She had also suffered from amenorrhœa and dysmenorrhœa and had been under treatment on and off for the whole period of five years. At 9 P.M. on the previous evening she had a supper of hashed meat and half an hour later was seized with sudden severe pain in the epigastric region which was worse than she had ever experienced. She was given some brandy which she at once vomited, and shortly afterwards she vomited again, but there was no blood in the vomited matter on either occasion. As the pain became worse and as she was obviously very ill Dr. Percy Edmunds was summoned. He saw her three-quarters of an hour after the onset of acute symptoms and found her suffering then from pain almost entirely confined to the neighbourhood of the scapulæ and clavicles, and he also noted that her face was markedly of the "abdominal" type He diagnosed a perforated gastric ulcer, administered two grains of opium, and advised her immediate removal to the hospital.

On admission the patient appeared to be seriously ill. Her face was very pale and drawn and she complained of pain in the back between the shoulders and in the epigastric region, but it did not seem to be very severe; there was no retching or hiccough. The pupils were not contracted. The pulse was 120 per minute, of very poor volume, and occasionally dicrotic, the respirations were increased in frequency, short and grunting in character, and the temperature was 100° F. The abdomen was somewhat distended and moved very little with respiration; there was considerable muscular rigidity on palpation, especially in the epigastrium and below the right costal margin, but very little tenderness. There was no dulness in the flanks and no fluid thrill was to be obtained; a tympanitic stomach note could be obtained on percussion over the left lower ribs nearly to the level of the umbilicus; the liver dulness was present down to the right costal margin.

Mr. Kellock saw the patient at 2 A.M. and decided on immediate operation. The abdomen was opened by an incision in the middle line reaching from the xiphisternum to the umbilicus. On opening the peritoneum a fair quantity of thin turbid whitish fluid escaped. On drawing up the left lobe of the liver the stomach was seen to be somewhat distended, its anterior surface was covered with lymph, and the vessels were intensely congested. The lesser curvature was fixed by adhesions so that it could not be drawn up. On examination of the upper border a perforation of about the size of a sixpence was found near the cardiac end, through which gas and fluid came when the stomach was manipulated. The edges of the perforation and the wall of the stomach in its neighbourhood were very hard and indurated. Owing to the density of the adhesions the closing of the opening had to be done without bringing it up to the surface; the edges were first brought together by fine silk interrupted sutures and a row of Lembert's sutures was then inserted, turning in the peritoneal and muscular coats of the stomach all round the perforation. The peritoneal cavity was cleansed by means of sponges, very little extravasation of the contents of the stomach being found except at the upper part in the immediate neighbourhood of the stomach and liver. A rubber drainage-tube was inserted leading down almost to the site of the perforation, the peritoneum was closed round it by a continuous silk suture, the skin and muscles were united by silkworm gut and horsehair sutures, and a dressing of cyanide gauze and sal-alembroth wool was applied.

The patient bore the operation very well; on its completion she was given a quarter of a grain of morphia hypodermically, after which she was very quiet for some hours and free from pain; she vomited slightly once, bringing up some greenish fluid. Eight hours after the operation the pulse had fallen to 96 per minute, the facial expression was improved, and the abdomen moved with respiration slightly more freely and was free from tenderness. A little blood-stained discharge came from the drainage-tube at first; on the second day a drain of iodoform gauze was substituted for the tube, and this was again changed on the third day for a strip of oiled silk which was continued for three days and then omitted as the discharge had practically ceased. For four days the patient was fed entirely by the rectum, plain water being given at first and subsequently peptonised milk and beef-tea. This was discontinued gradually and feeding by the mouth with milk-and-water was commenced. She suffered very little pain in the abdomen after the second day when it was relieved by a hypodermic injection of morphia. By Oct. 2nd she was having all her nourishment by the mouth; she was then given palatinoids of carbonate of iron and a little liquid extract of cascara sagrada. The stitches were removed on the twelfth day, the wound being soundly healed except where the drainage-tube had been. The temperature rose to 101° on the first day but subsequently was practically normal. The patient was sent to a convalescent home on Oct. 18th, the wound being then quite healed, her anæmia had much improved and she was taking a fair amount of solid food without pain or discomfort.

Remarks by MR. KELLOCK.—Owing to the early diagnosis that had been made in this case we were fortunately able to operate within five hours of the onset of the acute symptoms; the opium which had been given previously to the patient's admission to the hospital had, by relieving the pain, masked one of the important symptoms, but it probably helped very considerably in the successful issue by lessening the movements of the stomach and intestines and so prevented any great extravasation of the contents of the stomach. The history of the case, the rapid feeble pulse, and the rigid, almost motionless abdominal wall, combined with the marked abdominal facial expression, seemed to be sufficient evidence of what had occurred. The strong adhesions about the lesser curvature of the stomach rendered the suturing of the perforation difficult, as it had to be performed at some depth owing to the impossibility of bringing the organ to the surface without separating them; the density of these adhesions showed them to be of some standing, and it is quite possible that it was they that had given way at the time of the acute onset of symptoms and allowed the contents of the stomach to escape through a previously existing perforation in its wall. The limited area of peritoneum soiled by the contents of the stomach rendered the cleansing of the cavity easy and capable of being carried out with very little disturbance of the intestines and other viscera.

---

[1] THE LANCET, March 17th, 1900, p. 748.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A CASE OF CHONDRO-CARCINOMA OF THE RIGHT TESTIS, FOR WHICH CASTRATION WAS PERFORMED.

(Under the care of Mr. T. VINCENT JACKSON.)

MANY tumours of the testis are found to contain portions of cartilage embedded in their substance, and the only other organ which is similarly affected with equal frequency is the parotid gland. Another pathological bond of connexion between these two organs is the fact that the inflammatory process in mumps is liable to involve both of them. Malignant growths may arise in healthy tissues or they may involve, as in the case recorded below, non-malignant tumours; and in such cases the malignant growth has probably attacked the pre-existing tumour because of its low power of resistance.

A man, aged 40 years, was sent to Mr. Vincent Jackson by Dr. Sydney Partridge and was admitted into the Wolverhampton and Staffordshire General Hospital on Sept. 9th, 1900, on account of a sarcocele of the right testicle. The patient was married and his circumstances were ample for his position in life. He had not been troubled with any particular care or mental anxiety, his health and appetite were good, and he had maintained his ordinary habit of body. There was a clean sheet as regards any hereditary tendency to malignant disease, and none of the present generation of his relatives had been victimised by this disease in any of its forms. The previous history was very incomplete, but the patient was decided on the fact that he had never suffered from syphilis or traumatism. His personal knowledge of the enlargement of the testicle dated back only seven or eight months; probably this is to be accounted for by the absence, or almost the entire absence, of any subjective symptoms. The growth, however, continued, and as the weight appeared to cause lumbar pain he sought advice.

On examination the testicle, supported by the left hand, appeared to the eye to be massive in size and in weight unusually heavy, and all over it was non-resistant, with no suspicion of fluid. There were no isolated masses of cartilage; the tumour was non-transparent; here and there subcutaneously a distended vein was visible. No glandular enlargement was detected either by superficial or deep pressure in the right inguinal region. The condition of the lumbar lymphatic glands was undetermined. The liver was not enlarged. No diagnosis was made as between sarcoma and carcinoma. The report as to the urine was favourable.

On Sept 12th, under an anæsthetic, the right testicle was removed, care being taken to detach with it as much of the cord as could be reached. The organ weighed over a pound and a portion was sent to the Clinical Research Association for examination and a report. On the 21st the scrotal wound had quite healed, and on the 26th the patient left his bed. On the 28th an unexpected incident occurred, for in the morning hæmoptysis supervened and every effort was made to determine the cause. All physical means, such as percussion and the use of the stethoscope and of the thermometer, were resorted to, but with a negative result, no evidence of tuberculous deposit being detected. Several specimens of sputum were examined and no tubercle bacilli were found. There was no disease or enlargement of the aorta. On Oct. 5th there was obtained from the Jenner Institute of Preventive Medicine, a 10 per cent. dilution of Koch's original tuberculin. An injection of 0 01 cubic centimetre diluted with 1 in 100 carbolic acid was given. On the 8th 0 05 cubic centimetre diluted as before with carbolic acid was injected. In each case, five hours after the injection, a rise of temperature to 99 2° F. took place, the general symptoms being *nil*. Dr E. O. Morland, house physician, undertook the above test assisted by Mr. S. Southall, house surgeon. The presence of tubercle having been negatived by every diagnostic test used, it was felt that the cause of the hæmorrhage might be a cancerous deposit of the lungs. On the 12th the patient wished to be discharged. The expectoration now consisted of a little mucus, containing occasionally a little blood. On Nov. 14th Mr. Jackson received an announcement from the patient's wife that her husband had died on Nov. 3rd from a severe and uncontrollable attack of lung-bleeding. Later, Mr. Jackson was instructed that the patient had been buried without any post-mortem examination of the lung [illegible]

Microscopical examination —Mr. J. H. Targett's report on the specimen sent to the Clinical Research Association is as follows: "This is a composite tumour of the testis, congenital in origin. There are nodules of cartilage, bands of unstriped muscle, and tubulæ lined with columnar ciliated epithelium. Some of the cysts are filled with laminated epithelium which is undergoing a keratoid change. But the strangest thing in the section is an apparent infection with recent tubercle. Groups of giant cells are seen resembling those of tubercle, though they may be of the nature of phagocytes, although it is certain that tumours of all kinds may become infected with tubercle. The tumour is malignant in its present condition, though starting probably in some congenital inclusion. The term 'chondro-carcinoma' is now sometimes applied to this variety of growth. In the absence of other evidence I should not like to speak definitely about the tuberculous infection. It is a very interesting specimen "

Remarks by Mr. JACKSON.—On carefully considering the report of the microscopical examination of the tumour it seems to be very difficult to classify it accurately, for it contains a mixture of dissimilar elements which renders it scientifically distinct from an ordinary example of cancer.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Chronic Mastitis and its Relation to Tumour Formation.—Broncho-œsophageal Fistula.—Hæmorrhagic Pancreatitis with Fat Necrosis.

A MEETING of this society was held on Dec. 18th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Mr. F. T. PAUL (Liverpool) read a paper on Chronic Mastitis and its Relation to Tumour Formation (illustrated by a lantern demonstration and *microscopic specimens*). He commenced by remarking that the tendency of chronic inflammation of the mammary gland to end in tumour formation was a fact by which he was more impressed every year. It was well known that cancerous breasts almost constantly showed microscopical changes indicating a preceding chronic mastitis, and that breasts removed for simple chronic mastitis frequently presented appearances suggestive of the commencement of cancer. The same was also true of innocent tumours, even of those occurring early in life. The varieties of chronic mastitis were discussed. In the tuberculous form of mastitis actinomycotic-like bodies were described as present in five or six cases. In the simple form of mastitis it was considered that there was no true pathological distinction between cases occurring in early life and those met with during the period when the breast underwent involution, as all the proliferative and cystic changes characteristic of the later form were sometimes present in the early kind. A case of marked bilateral chronic mastitis occurring in a girl, aged 18 years, and showing the cystic, intracystic, peri-acinous, and epithelial changes in an excessive degree was described. The histology of "involution mastitis" showed, said Mr. Paul, that it commenced as a chronic interstitial inflammation, passing into a cirrhotic change accompanied by cystic alterations in the acini, and generally by a considerable increase in the gland elements. At the stage of involution in some cases resolution took place; in others the irritation continued to be evidenced, especially in the peri-acinous connective tissue, which after prolonged stimulation might end in the growth of a fibro-adenoma. In other examples, or at other parts of the same organ, the epithelial structures responded chiefly, and intra-cystic papilloma or carcinoma might be originated. Attention was called to the following points: the association of chronic mastitis with adenoma in early life and also with the cystic and other varieties met with at a later period; to its almost constant presence in conjunction with mammary cancer; to the marked bilateral mastitis which precedes bilateral cancer; and especially to the highly suggestive appearances seen under the microscope in specimens of chronic mastitis. Taking these facts in conjunction with clinical experience it seemed certain that chronic inflammation of the breast, if not the actual cause, was at any rate the frequent predisposing cause of tumour change in the mamma and in Mr. Paul's opinion rendered excision desirable in all marked or inveterate cases.—The PRESIDENT said that he did not gather whether Mr. Paul regarded chronic mastitis as a precursor of all cases of cancer or whether that was only one mode in which it arose. The subject was interesting in relation to the possible parasitic origin of cancer. On the one hand Mr. Paul's view rather upset this hypothesis, but on the other chronic mastitis might be only a necessary condition to the parasitic growth.—Mr. RAYMOND JOHNSON remarked that he had examined a large amount of material with the object of determining if the form of mastitis met with in carcinomatous breasts was in any way to be distinguished from that met with under other circumstances. He had gradually come to the conclusion that the proliferative epithelial changes found in such cases, although very marked, were not distinctive. As to the close relation between carcinoma and chronic mastitis he had no doubt, but it seemed impossible to trace the one condition without interruption into the other, and it was probable that some other cause must be superadded to the mastitis to cause cancer. Mr. Johnson did not believe that the ordinary fibro-adenoma of the breast of young women was the result of chronic inflammation. He also remarked that in his experience there was no evidence that adenoma of the breast tended to undergo a transformation into carcinoma.—Mr. D'ARCY POWER congratulated Mr. Paul on his specimens. On looking at them carefully he could not fail to notice an essential difference between the parts which that gentleman had indicated as mastitis and those which he had indicated as cancer.—Mr. S. G SHATTOCK endorsed the view of those who thought that there was something essentially different between the inflammatory and carcinomatous processes. He asked whether the specimens had been stained for "cancer bodies." If these were present then the structure was cancer, but if not then it was not cancer. As regarded the "actinomycotic" bodies to which Mr. Paul had drawn attention, he asked if they had been submitted to any bacteriological stains and he proposed that they should be referred to the morbid growths committee. He differed from Mr. Paul in his view on tuberculous disease of the breast. He had long thought that the fatty changes of the epithelium in mammary carcinoma were of the physiological kind. He had, however, tested many mammary carcinomata for the reaction with rennet, but in all cases with a negative result.—Mr. PAUL, in reply, confessed that he could not see his way at present to subscribe to the parasitic theory of cancer, though he was quite willing to do so when sufficient evidence was brought forward. "Cancer bodies" had not been tested for in the specimens. On the whole he agreed with Mr. Raymond Johnson that there was a gap between chronic inflammation and cancer and he did not believe that chronic inflammation went straight on to cancer without a break.

Dr. J. H. DRYSDALE exhibited a specimen of Broncho-œsophageal Fistula derived from a girl, aged 17 years. At the age of three years she had swallowed a shilling. She was admitted to hospital on account of the vomiting which occurred every time she took food, the vomit containing mucus and pus with food. At the necropsy an opening was found on the anterior surface of the œsophagus leading through the bronchus into a cavity at the apex of the left lung.

Mr. H. A. SCHÖLBERG exhibited specimens from a case of Hæmorrhagic Pancreatitis with Fat Necrosis. On Nov. 18th, 1900, the patient had been suddenly seized with severe pain and vomiting. He was admitted to hospital on the 22nd; the diagnosis pointed to gastritis. Eight days later he died suddenly. At the necropsy all the fat connected with the intestines showed fatty necrosis. The pancreas was thickened and matted to the tissues in front of it and it was the seat of hæmorrhage. The patient had during life a large quantity of sugar in the urine, but he was stout and had exhibited none of the other signs of diabetes. Most of the cases of hæmorrhagic pancreatitis which had been reported had been mistaken either for peritonitis or for intestinal obstruction, but this case did not present the symptoms of those conditions.—In reply to Dr. ROSE BRADFORD Mr. SCHOLBERG said that there was no embolism of the splenic artery. All the arteries of the abdomen were normal. There was no fatty necrosis in any other part than the body.

CLINICAL SOCIETY OF LONDON.

Ankylostomiasis.—Hæmatoporphyrinuria.—Pyo-pericarditis Treated by Incision and Drainage.—Concretions of Uric Acid in Gonorrhœal Rheumatism.

A MEETING of this society was held on Dec. 14th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. W. J. TYSON (Folkestone) read a paper on a case of Ankylostomiasis. The patient, a man, aged 34 years, had for the past 15 years lived in China and had been quite well until May, 1899, when he was told that he was suffering from malaria. At this time he was living in Singapore. Subsequently he became very anæmic and suffered from indigestion. He noticed that his stools were often reddish in colour and attacks of faintness were common, with much breathlessness and palpitation on the slightest exertion. He also had dimness of vision, with partial loss of hearing. During a sojourn of 14 days in Singapore, on his way to England, the malarial parasite was discovered in the blood, and on account of the excessive anæmia the fæces were examined and there was found in them the ova of ankylostomum duodenale. A course of thymol was carried out on board ship, but the result was not satisfactory. Three doses of the drug of 10 grains each were given. Dr. Patrick Manson saw him on his arrival in London and confirmed the diagnosis of ankylostomiasis. He advised a course of thymol and placed him under the care of Dr. Tyson. He was admitted into the Folkestone Hospital on Sept. 23rd, 1899, suffering from severe anæmia. There were no enlargement of the liver or of the spleen, no œdema, and no retinal hæmorrhages. He complained of pain in the epigastrium and of insomnia. On Sept. 24th two doses of Carlsbad salts were given in the morning, and when the bowels had acted then thymol was given in 30-grain doses every two hours on four occasions, 120 grains in all. During its administration the bowels acted several times. At 7 P.M. a further dose of Carlsbad salts was given and the bowels again acted. On examination of the fæces a large number of worms and ova were found. The thymol produced, with the exception of a feeling of sickness, no unpleasant effect. A week later the same treatment was repeated on account of two or three worms being found in the motions. He made a rapid and complete recovery. Dr. Tyson remarked that this parasite should be remembered as a cause of progressive and obstinate anæmia. The large doses of thymol had an extraordinary effect on the parasite, but apparently did not affect the patient in any poisonous way. It was interesting to note in this case the presence of the malarial parasite with the ankylostomum duodenale; it was not uncommon for the two parasites to dwell in one host. When this was so it was important to settle the relative value of each cause, for the administration of thymol was not a suitable treatment for malarial disease or for any other form of anæmia.—Dr. F. S. TOOGOOD remarked that the presence of the malarial parasite in Dr. Tyson's case was very interesting in its bearing on the disease known as kala azar. This was a very fatal malady which was always endemic and sometimes epidemic in the tea-planting districts of Assam. It was long thought to be due to the presence of the ankylostoma, but Major G. M. J. Giles, A.M.D., had shown that although the parasite was present in many of the cases yet the disease was essentially malarial. The spleen was often enormously enlarged and examination of the blood revealed the malarial parasite and great diminution of the white corpuscles as well as of the red corpuscles. The ankylostomiasis was treated by the administration of thymol which usually caused much pain and often vomiting.—Dr. TYSON, in reply to the PRESIDENT, said that the thymol had been given in cachets. It was necessary to give large doses to produce the desired effect upon the worms. To avoid the poisonous effects the bowels must be very freely moved and all forms of alcohol in which thymol was soluble must be avoided.

Dr. JAMES CALVERT communicated a paper on a case of Hæmatoporphyrinuria not due to Sulphonal (with a report on the urine by Dr. A. E. Garrod). The patient, a woman, aged 32 years, single, was admitted on Jan. 15th, 1900, into St. Bartholomew's Hospital for hæmatemesis which had occurred on Jan. 13th. She had a history of indigestion and the diagnosis was gastric ulcer. As no urine was passed during the six hours after admission a catheter was used and 20 ounces of dark, cherry-coloured urine were drawn off. The urine was faintly acid and its specific gravity was 1016. No albumin, no sugar, no blood, no bile, and no casts were present. The spectroscope showed the bands of hæmatoporphyrin. The patient noticed the dark urine on Jan. 14th, but she said that "it was all right before then" She had passed similar dark urine about a year before this attack. At that time she was suffering from indigestion, but she had no hæmatemesis and, so far as she knew, no melæna. She denied taking any sulphonal and her medical attendant wrote to say that he had never given her the drug. On Jan. 19th an examination of the blood was made: hæmoglobin, 48 per cent.; red blood corpuscles, 2,292,000; *and white blood corpuscles, 8500.* On Jan. 23rd another blood examination was made: hæmoglobin, 54 per cent.; red blood corpuscles, 3,880,000; and white blood corpuscles, 11,000. On Jan. 25th the blood examination was as follows: hæmoglobin, 62 per cent.; red blood corpuscles, 3,968,000; and white blood corpuscles, 11,000. After this the percentage of hæmoglobin and the number of the red corpuscles steadily increased, and the urine gradually returned to its natural colour. Throughout the case the hæmatoporphyrinuria did not appear to give any manifestations of its own. All the symptoms present could be attributed to the hæmatemesis. The patient made an uninterrupted recovery and she left the hospital on March 8th. Dr. Calvert remarked that eight cases of hæmatoporphyrinuria not due to sulphonal poisoning had been recorded. They were mentioned in Dr. A. E. Garrod's article in the fourth volume of the Encyclopædia Medica. They all ran a favourable course with the exception of Ranking and Pardington's two cases which occurred at the same time in different rooms of the same house. These two cases were severe, presenting symptoms similar to those of sulphonal poisoning, which, however, was carefully excluded—one of these patients died and the other recovered. There was no post mortem examination on the fatal case. The fact that the hæmatoporphyrinuria occurred after hæmatemesis was interesting because Professor B. J. Stokvis held that hæmatoporphyrinuria occurring in sulphonal poisoning was due to the absorption of altered blood from hæmorrhages produced by the drug in the mucous membrane of the stomach and intestines, a view which was opposed, among other things, by the circumstance that such hæmorrhages were by no means constantly found at the post-mortem examination of these cases. The blood counts were instructive, showing as they did the increase of hæmoglobin and of red blood corpuscles occurring together with the hæmatoporphyrin in the urine. In its general characters the urine which was passed closely resembled sulphonal specimens. Hæmatoporphyrin was present in considerably larger amount than in ordinary morbid urines, but, as in sulphonal cases, the abnormal *colour of the urine was chiefly due to other less* known pigments. The hæmatoporphyrin could be removed by the soda method and after its removal a purple pigment could be extracted which did not agree in properties with any known urinary colouring matter. To this pigment the colour of the urine appeared to be mainly due. Owing to its instability the purple pig*ment could not be obtained in a state of purity*, as it was changed by heat and could not be extracted by ordinary solvents such as chloroform, ether, or amylic alcohol.—Dr. A. E. GARROD remarked that the case was of interest because of the rarity of hæmatoporphyrinuria apart from the administration of sulphonal and because of its association with hæmatemesis. He thought that the urinary condition was not really dependent upon this latter condition, as in several cases of hæmatemesis and melæna he had failed to find any unusual amount of hæmatoporphyrin in the urine. Another point of interest was the steady increase of red corpuscles and hæmoglobin in the period during which hæmatoporphyrinuria was observed. This lent further support to the view that the excessive excretion of this pigment was due to a perversion of the processes disposing of effete hæmoglobin rather than to an unduly active hæmolysis.—Dr. W. H. B. BROOK (Lincoln) referred to a case of hæmatoporphyrinuria which he had seen 12 years ago in which no sulphonal had been administered. The patient was suffering from pernicious anæmia. In that case there was found to be a very great excess of the aromatic sulphates over the inorganic sulphates.—Dr. CALVERT, in reply to the PRESIDENT, said that the hæmatemesis was due to gastric ulcer. No estimation of sulphates in the urine had been made.

Dr. JOHN FAWCETT and Mr F. J. STEWARD communicated a paper on a case of Pneumococcal Suppurative Pericarditis treated by Incision and Drainage. The patient was a boy, aged eight years, who was admitted into Guy's Hospital on July 16th, 1900. Illness began on July 10th. On admission there were signs of lobar pneumonia at the right base. Signs of pericarditis were first noted on July 17th. Ten days later the pericardium was explored as the evidence of infusion had increased and the boy's general condition had so deteriorated that it was thought the effusion was possibly purulent. The area of dulness reached above the first intercostal space one inch to the right of the sternum and to the left two inches *external to the nipple*; there was also marked tenderness of the epigastrium on pressure Pus having been found on exploration the pericardium was incised and drained by removal of a portion of the fifth left costal cartilage. After operation the boy's condition much improved, but 14 days later a small localised empyema of streptococcal origin was found on the right side The necropsy showed that the condition of the pericardium was rapidly clearing up and that as far as it was concerned the result was most favourable. It was almost certain that had the patient not developed a streptococcal empyema he would have survived, but he was a very thin, ill-developed boy, and so a most unfavourable subject for so severe a series of infections. *Early incision with drainage* was certainly the correct treatment for there cases; 45 cases of suppurative peritonitis thus operated on had been recorded, and 16 of the patients (35·5 per cent.) had recovered. Dr. Fawcett remarked on the absence of friction sound, which had been frequently listened for in this case. The temperature gave no indication of the suppuration within the pericardium.—Mr. E. P. PATON referred to a case which he had under his care five years before in which he regretted that drainage had not been carried out. It was a case of acute infective osteo-myelitis of the humerus, complicated by a large collection of pus in the pericardium. Aspiration was first performed and pus was drawn off, the patient being thought too *ill for further operation*. The patient became very ill on the next day, and when almost moribund the house surgeon, suspecting re-collection, attempted to repeat the aspiration and inserted the needle on the right side of the sternum The patient died shortly and it was found that the left auricle had in some unaccountable way been wounded on its posterior aspect.—Dr. W. C BOSANQUET remarked that considerable difficulty attended the diagnosis of pus in the pericardium and he asked what were the signs upon which Dr. Fawcett relied. He also asked whether it was possible to do operations upon the pericardium under local anæsthesia such as that produced by cocaine. He had been particularly struck with the large number of cases of pericarditis which had occurred during the past year in the Charing Cross Hospital amounting to four or five times the normal number. He would like to know what was the experience at other hospitals and whether any cause could be suggested. In such cases as had been examined the pneumococcus was certainly the most frequently occurring organism. This organism had a marked proclivity to the pericardium in children and in young people.—Mr. F. C. WALLIS thought that local anæsthesia was most advisable in such cases. Where general anæsthesia had been employed the result in his experience was mostly fatal. He regarded eucaine as decidedly preferable to cocaine. The latter had distinct toxic effects which were not observable in eucaine. He had used as much as four drachms of a 4 per cent. solution of eucaine without any evil effect, and he had even excised rib under local eucaine anæsthesia. He trusted that operations upon the pericardium would be more frequent. In reply to the PRESIDENT he said that he had used cocaine both for adults and children.—Dr. PERCY KIDD referred to a case of suppurative pericarditis in which several drachms of a 4 per cent. solution of eucaine had been injected and swabbed about the parts. Most pain had been experienced when the pericardium was taken up with the forceps and experimental researches had shown that this membrane was acutely tender. The absence of a friction sound was unusual in suppurative pericarditis, and he mentioned an interesting case in which after death a pericardial suppuration was discovered, though there were no signs during life.—Dr. A. F. VOELCKER asked if the brain had been examined in the case under discussion. In cases due to the pneumococcus death was aften brought about by meningitis. Cases of pneumococcus infection were often complicated by pleuritis, in which the exudation was so thick that nothing could be drawn off by the needle; and he suggested that in such cases where the pneumonia did not resolve it would be advisable to open the pleura and drain it.—Dr. A. E. GARROD remarked that suppurative pericarditis was difficult to diagnose in adults, but it was even more so in young children, and any means which helped to clear this difficulty was of value.—The PRESIDENT asked if a preliminary puncture had been made prior to the operation. The general symptoms of suppurative pericarditis as of empyema were most misleading. The chart, for instance, of the case under discussion gave no indication of suppuration and profuse sweating often occurred in children with simple serous exudation. He asked what cause could be traced and whether there had been previous cases in the same house.—Mr. ARTHUR BARKER agreed with the value of eucaine and local anæsthesia, but the emotional condition of children must not be forgotten, and on this account local anæsthesia was not always available. A certain fortitude on the part of the patient was necessary and he referred to a case in point.—Mr. WALLIS added, in reply to the PRESIDENT, that in using local anæsthesia for children he had sometimes adopted the method of blindfolding them and using local freezing for the needle puncture.—Dr. FAWCETT, in reply, referred to the difficulty in diagnosing suppurative pericarditis. In his case the symptoms, which had enabled him to come to that conclusion, were the increase in the pericardial dulness, the progressive anæmia and wasting, and finally an acute tenderness at the lower end of the sternum. An exploratory puncture had been made prior to the operation in the fourth interspace one inch to the left of the sternum. The etiology of his case was obscure; there had been no cases in the same house. His belief was that the brain had been examined but nothing had been found.

Mr. W. G. SPENCER read a paper on a case of Gonorrhœal Rheumatism, with bursæ which were filled with concretions of urate of soda. The patient was a coloured man, aged 33 years. He had suffered 14 years previously from gonorrhœa and 10 years ago he had a stricture which was divided under anæsthesia. No instrument had been passed into the urethra since. For six or seven years he had suffered from attacks of spasmodic pain in his legs, lasting two or three weeks at a time, especially in August and September (in Demerara). During the attacks the knees were stiff. Six years ago a swelling formed on the dorsum of the left foot, then over the tubercle of the left tibia, and then on both sides of the heel. The patient's habits were temperate and there was no family history of gout. On his arrival in this country he was unable to walk; the skin over the knees was red, shiny, hot, and tender, and the joints could not be moved without pain. Examination revealed the existence of a spasmodic stricture at the membranous urethra. The patient was treated for a time by dilatation of the stricture and the joints improved, but the bursæ remained unaltered. The latter were explored and search was made for gonococci, some thick, white, semi-solid material being withdrawn, which proved to be sodium biurate free from organisms. He left the hospital six weeks later. Mr. Spencer suggested that the concretions in the bursæ owed their existence to the gonorrhœal inflammation.—Mr. GEORGE EASTES asked what were the grounds upon which the bursal condition had been associated with the gonorrhœa. He doubted the connexion. Might it not be that the urate of soda had been deposited before the patient had been attacked by gonorrhœal rheumatism?—Mr. SPENCER, in reply, remarked that they had to rely upon the history of the patient.

OPHTHALMOLOGICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held on Dec. 13th, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Mr. J. H. FISHER showed a case of Congenitally Imperfect Separation of the Iris from the Back of the Cornea. The patient was a woman, aged 27 years, who had been treated recently at the London Hospital for an attack which appeared to be one of acute or subacute glaucoma. On examination the whole anterior surface of the left iris was pitted. At the outer and lower part there was a wide adhesion of the iris to the back of the cornea, while on the inner side it was adherent to a less extent. Mr. Fisher worked out the refraction under hematropine with the result that the tension rose to + 1. There was pain and the pupil remained dilated, although that of the right eye had regained its normal condition by the next day. He considered that this case threw some light on congenital glaucoma, as the position of the iris here clearly was the cause of the increased tension.

Mr. W. T. LISTER exhibited a large Dermoid Tumour on the Cornea of an Ox, extending to the Sclera, from which grew a Bunch of Long Hairs.

Mr. G. T. BROOKSBANK JAMES showed:—1. A rare example of Persistent Papillary Membrane. The patient was a child, aged eight years, who attended on account of a convergent squint. She was one of a family of four, none of the others having any eye affection. When the patient was 16 months of age there was a slight inflammatory attack which lasted a few days only. In the right eye there was a convergence of 40 degrees. The iris was of a pale greyish yellow colour. The normal pupil was occupied by strands which inclosed several openings. In the left pupil there were some small tags of pupillary membrane, though vision in the eye was good in spite of five dioptres of hypermetropia. In the affected eye the vision was extremely bad but the projection was good. 2. A boy, aged 11 years, who with his Hypermetropia Corrected had Normal Vision. In the fundus there was a large pigmented area below the disc which had a crescent. The pigment was mostly under the vessels but near the disc they dipped into it. There was also a strand of persistent pupillary membrane. Mr. James referred to some cases shown by Mr. Sydney Stephenson which exhibited somewhat similar changes.

Mr. A. STANFORD MORTON showed a Growth on the Cornea in a boy, aged seven years, who was first seen in August, 1900. At the upper corneal margin there was a yellowish spot four millimetres in diameter; it was not raised above the corneal margin and it extended downwards to about the margin of the undilated pupil. He tried to shave it off, but failed to do so. He then transfixed it and entered a space full of yellowish material which he scraped out. It was found on examination to consist of connective tissue with some elastic fibres but no fat. On the deep surface of the parts removed was some cellular material in which there appeared to be a few giant cells, but there was nothing typical of tubercle. It certainly was not congenital and it continued to spread but very slowly.—Mr. E. NETTLESHIP referred to a case which he had seen with Mr. T. H. Bickerton which was somewhat similar, and here after a time it ceased to grow.—Mr. G. H. GOLDSMITH also referred to a somewhat similar case.

Dr. A. H. THOMPSON exhibited a case of Superficial Choroidal Atrophy without subjective symptoms in one of a family the members of which were subject to night-blindness. The patient was a woman who made no complaint of her vision which was found on testing to be $\frac{6}{9}$ in one eye and $\frac{6}{6}$ in the other. The maculæ were normal and the fields were full. In each eye there was a large area of choroidal atrophy; there was, however, no night-blindness or diminished light sense. This patient's father had difficulty in seeing objects, though he could see to read small print, and there were several members of the family who suffered from night-blindness.—The PRESIDENT had found that many of these patients derived very great assistance from wearing glasses of a golden-yellow tint, and he thought that the cutting off of the violet rays by glasses of this colour might be the explanation of this, although they did not help all cases.—Mr. EDRIDGE-GREEN thought that it would be interesting to see if this patient saw with the macula as quickly as a person with normal sight. He had tried the golden-yellow glasses and in a dim light he at first saw better with them, but after wearing them for some time he certainly saw no worse when he removed them.—Dr. TEMPEST ANDERSON discussed the use of yellow glass employed in the photographic camera when taking a picture of the sky and clouds.

Dr. W. O. ROCKLIFFE exhibited an instance of Conjunctival Growth; (?) Pinguecula. This patient, aged 12 years, was first seen in August, 1900. The mother of the patient stated that at birth a small red pimple was noticed at the outer side of the left cornea and it had slowly spread since then. A crescentic pigmented thickening surrounded the outer third of the cornea which was two millimetres in thickness. It was freely moveable with the cornea and had no deep attachment, so that a probe could be passed beneath it It had not enlarged to an appreciable extent during the last three months. There was a tuberculous history, but a piece which he had removed for examination had not yet been reported upon. The fundus was normal and the vision was $\frac{6}{6}$. Dr. Rockcliffe stated that he did not think it malignant and he mentioned a similar case shown to the society by Dr. W. J. Collins. In the *Ophthalmic Review* for October was an abstract of a paper by Le Grange in which he stated his belief that these growths were usually of a dermoid nature and that they contained hairs, but in this case no hairs were present. Dr. Rockcliffe stated his intention of dissecting it out.

Mr. R. MARCUS GUNN showed a case of (?) Tubercle beneath the Ocular Conjunctiva. The patient was a girl, aged 13 years, beneath the conjunctiva of whose left eye near the cornea was a vascular growth. She had tuberculous glands, but there was no family history of tubercle.

Mr. J. H. FISHER exhibited a Sarcoma of the Conjunctiva. The patient was a man, aged 28 years, who had been invalided out of the army on account of the eye. In May of last year he first noticed a small red spot which grew and was removed in February of this year. It was removed again in May and also in August for recurrence. There was now a flat yellowish-brown mass which was smooth on the surface and vascular. About one-fifth of the cornea was covered, but the vision was good. There was no glandular enlargement and no specific history. Mr. Fisher proposed to remove the eye, with the growth, as partial operation had proved to be useless.

Mr. C BLAIR showed an unusual case of Choroiditis. The patient was a woman whose sight had been affected for about three months. Her vision now = J. 20. There was an area of closely-packed choroiditis with almost an entire absence of pigment. The patches were not raised and the field of vision was defective. The vitreous was full of opacities, but there was no specific or tuberculous history.—Mr. W. H. H. JESSOP always looked upon these cases of vitreous opacities as being syphilitic and thought that this case was really of that nature.—Dr. C. O. HAWTHORNE also mentioned a case.

Mr. W. T. HOLMES SPICER showed a Nævus of the Orbit. The patient was a married woman who, when seen in July, 1893, had some proptosis of the left eye due to a vascular tumour. In August of that year Mr. Spicer performed electrolysis without any immediate result In January, 1899, he again electrolysed the organ. The patient became pregnant and during this time the nævus increased greatly in size. A hard mass was then felt and on cutting into this it was found to be an old blood cyst. Shortly after the cornea ulcerated and the eye was excised. Mr, Spicer then sent the patient to Dr. H. Lewis Jones who considered that owing to the apparent free communication of the growth with the cavernous sinus electrolysis was not safe —Mr. W. A. FROST suggested that pressure might be beneficial.—The PRESIDENT thought that the growth had better be left alone owing to the danger of cutting into so vascular a structure.

BRITISH GYNÆCOOLOGICAL SOCIETY.

Exhibition of Specimens.—Four Abdominal Cases.—Circulatory Phenomena as Sequelæ of the Pregnant Uterus.

A MEETING of this society was held on Dec. 13th, Dr. W. J. SMYLY, the President, being in the chair.

Mr. J. FURNEAUX JORDAN (Birmingham) showed specimens (1) of Carcinoma of the Ovary, and (2) of Tubal Gestation, removed by vaginal cœliotomy.

Mr. F. BOWREMAN JESSETT and Mr. W. BALGARNIE showed a specimen of Tubal Gestation removed by Abdominal Cœliotomy.

Dr. HERBERT SNOW showed a specimen of Pyonephrotic Kidney ruptured by the fall of a picture in a case of uterine carcinoma.

Dr. P Z. HEBERT showed a specimen of a Nine-weeks Embryo in an intact amniotic sac.—Dr. HEYWOOD SMITH, Dr. SNOW, Dr. J A. MANSELL MOULLIN, Dr. W. JAPP SINCLAIR (Manchester), and the PRESIDENT took part in the discussion on these specimens.

Dr. GEORGE ELDER (Nottingham) read short notes of Four Abdominal Cases, with comments. The first was a case of acute gonorrhœal salpingitis, in which, after palliative treatment had been tried without success, the tubes were resected by abdominal section, the ovaries being allowed to remain. The second case was that of a very large renal cyst, with the symptoms and signs of an ovarian cyst with twisted pedicle. Repeated examination of the urine had failed to detect any abnormality in it. The third case was one of hysterectomy for a large fibroid, in which the patient made a good recovery, but a week after her return home was taken very ill with renal symptoms, from which she died four weeks later. The cause of death was apparenty septicæmia. The fourth case was the later history of a patient whose ovaries and tubes were removed in 1894 for papilloma She continued in very good health until the end of last year, when she was lost sight of.—Mr. BOWREMAN JESSETT said that he had reported a case very similar to the second one mentioned by Dr. Elder at a meeting of the society some weeks ago, whilst the third case found a parallel in a case described by Dr F. A Purcell two years ago.—Mr. CHARLES RYALL, referring to the first case, said that it was very difficult to know how to advise men who had had gonorrhœa as to when it was safe for them to marry, especially when they had a chronic gleet, for it had been repeatedly proved that the disease might lurk, not only in the anterior urethra, but also in the posterior urethra and in Cowper's glands.—Mr. SKENE KEITH remarked that he had seen a case in his father's practice very similar to the one of hysterectomy reported. The patient did well for some days after operation, except that she was very flushed and somewhat cyanotic. She died some weeks after getting home, and the post-mortem examination showed that there was hardly any kidney substance left.—Dr. JOHN SHAW, in speaking of the first case, said that although the symptoms and sequelæ were very like those of gonorrhœa, he had seen cases of salpingitis, especially of hydrosalpinx, on one or both sides in young women as a result of excessive sexual intercourse Such a condition usually got quite well under hygienic treatment.—Dr. SINCLAIR observed that 10 or 12 years ago he had a case of papilloma of both ovaries. He was under the impression at the time that the condition was a malignant one. But he saw the patient in the early part of last year and she was then quite well In another case the pelvis was so overgrown with papillomatous masses as to resemble a bird's nest; but the patient made a good recovery, and although this was five or six years ago, she had since remained quite well.—Dr ELDER replied

Dr. R H HODGSON read a paper on Circulatory Phenomena as Sequelæ of the Pregnant Uterus.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Dec. 6th, Dr. W. H. LAMB, the President, being in the chair.

Mr. EDMUND ROUGHTON showed a man who complained of Sciatica. He had a large gumma in the gluteal region. At present it had not yielded to large doses of iodide. Mr. Roughton proposed to give mercury as well.—The case was briefly discussed by Dr. A. EDDOWES, Dr. ERIC PRITCHARD, Mr. H. W. PAGE, and Mr. RAYMOND JOHNSON.

Dr. YULE read notes of and showed (for Dr. LEONARD GUTHRIE) a case of Alexia due to "Word" and "Letter Blindness." The patient, a man, aged 53 years, had an attack of repeated retching lasting 24 hours on Sept. 29th, 1900. On the following day he found that he could not read aloud or understand the meaning of printed or written matter. He could speak well enough for ordinary purposes, but frequently found himself at a loss for common words, and he often forgot the names of common objects. He could tell the time correctly by the clock, count money, read Arabic and Roman numerals, and do simple sums in arithmetic. His intellect generally and his memory for events, recent and past, were unimpaired. He had no paraphasia or motor aphasia, no "word-deafness," no hemiplegia, and no hemianæsthesia. Dr. Rayner Batten reported that his optic discs, fields of vision, and colour sense were normal. He had no headaches or other cerebral symptoms. He had contracted syphilis 20 years previously. His symptoms at present were inability to read or understand written and printed language and a certain degree of loss of memory for words and names of common articles. Thus, for example, he named "watch," "key," and "pencil" correctly, but could not name a "hand-bell" although he knew what it was. He called eye-glasses "spectacles," but was aware of his mistake. If asked to read aloud he recognised and uttered correctly a few words here and there, but seldom in sufficient number to make sense. Sometimes he guessed a word when he knew its context, or perhaps from its general shape and appearance; sometimes he substituted another word for it more or less resembling it in meaning or sound. His chief trouble was obvious when he attempted to spell a word at sight or to copy it, for he then mistook various consonants for each other. B's, p's, r's, m's, and n's were confused and the result in each case was a nonsense word. He copied "tumbler" as "tunrer" and "pocket" as "roecket," and of course attached no meaning to either word. In copying, also, he left out words and whole lines. Vowels were usually copied correctly. He could write easily from dictation and also spontaneously, spelling fairly well for a man of his education, but after an interval he was unable to read or copy his own writing. Sometimes after prolonged scrutiny the meaning of a word seemed suddenly to dawn upon him; sometimes he spelt it letter by letter and in time got it right. In commenting upon the case Dr. Guthrie remarked on the rarity of uncomplicated word- and letter-blindness and on the fact that it was a complaint from which the uneducated were exempt. Had the patient never learnt to read or to write he would not have known that there was anything the matter with him. At most he would have complained of slight loss of memory for words and names of objects. The various causes of alexia were enumerated, such as motor aphasia, especially in those who could only understand print by framing the words with lips and tongue or uttering them *sotto voce;* verbal amnesia, in which the patient had forgotten the names of the words which he saw; hemianopia; and word-deafness in "auditives" who hitherto had always seemed obliged actually to hear words seen in print in order to understand them. In the present case alexia was proved to be due to word- and letter-blindness by the patient's inability to copy. The freedom from difficulty in reading numerals was not uncommon in such cases and had led to the belief that there was a separate centre for storage of mental images of numerals apart from that for letters and words. It seemed more probable, however, that the images of numerals were retained because they were few compared with those of letters, being nine only as against 52. A similar explanation would account for his recognising vowels better than consonants. The region involved was probably the left visual word-centre situated in the angular gyrus and possibly a part of the supra-marginal convolution. The partial loss of memory for words and names pointed to an affection of the left auditory word-centre in the superior temporal convolution, not sufficient to cause word-deafness. The history of prolonged retching immediately preceding word-blindness made it probable that hæmorrhage from a syphilised vessel in the neighbourhood of the left visual word-centre had occurred. In most cases of the kind, however, thrombosis was the lesion found.

Dr. ALFRED EDDOWES showed a girl, aged 17 years, who presented a condition resembling Lichen Simplex Chronicus extending in a narrow band from the spine to the point of the shoulder, thence in a more broken line down the arm and obliquely across the hand to the first, second, and third fingers. The lesion commenced from eight to nine years ago as an eczema on the back of the hand. As this starting point became worse, apparently as the result of scratching, the disease spread upwards in the above-mentioned line which suggested at first sight the distribution seen in ichthyosis hystrix or nævus linearis, but it was cleaner looking than the latter. Microscopically the papules had much the appearance of lichen planus, but the cell-infiltration surrounded the hair follicles which formed the centre of each papule. The affection which had recently been treated by cauterisation had proved far more rebellious than the more commonly met with patches of lichen simplex chronicus. The extraordinary interest of the affection consisted in its distribution, considering that it was not congenital in origin. Various theories were discussed to explain how such could occur otherwise than as a congenital defect.

Mr. D'ARCY POWER showed a man, aged 64 years, with a Sacculated Swelling on the Radial Side of the Palmar Aspect of the Wrist. The swelling was freely moveable and lobulated. It possessed a well-marked pulsation which was slightly distensile. The swelling appeared three months ago and had gradually increased in size. The patient was a labouring man who had never worn a wristlet and had sustained no injury to his wrist. Mr. Power thought that the question of diagnosis was one of interest and lay between a sacculated radial aneurysm and a ganglion of the sheath of the supinator longus tendon over which lay an enlarged and thickened artery. The aneurysm appeared to him the less likely as such a condition in the radial artery was rare apart from injury and embolism. He proposed however, to cut down upon the tumour and treat the condition he found. But in any case the case enforced the necessity of a careful examination of such swellings in the neighbourhood of arteries before they were incised or an attempt was made to disperse them.—Mr. ROUGHTON thought that the pulsation was not distensile and that the tumour, although fluid, was not compressible. He felt pretty sure that it was a ganglion.—Dr H. A. CALEY considered that the free mobility of the swelling, its lobulated outline, and the fact that the pulsation was not definitely expansile were against its being aneurysmal. The tense feeling on compression told in the same direction and suggested that it was a ganglion intimately connected with the radial artery.

Mr. HUBERT PHILLIPS showed a case of severe Bromide Rash in an Epileptic.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Hæmatocolpus and Hæmatometra.—Inflammatory Conditions of the Colon associated with Septic Abdominal Disease.—Acute Parenchymatous Glossitis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Dec. 4th, Dr. GORDON BLACK, the President, being in the chair.

Dr. J. B. HELLIER read notes of a case of Hæmatocolpus and Hæmatometra due to atresia of the hymen. The patient, who was 15 years old, showed signs of puberty. The vagina was distended so much that it formed a cystic swelling which reached above the navel. The distended uterus formed a small cystic swelling above the hæmatocolpus. At the vulva there was a protrusion formed by the bulging out of the imperforate hymen. The patient had enjoyed perfect health and the condition was discovered accidentally. The case was treated by slow evacuation of six pints of inspissated menstrual fluid and by the subsequent excision of a circular portion of the septum, followed by drainage and irrigation. The patient made a good recovery and she had menstruated normally since. Dr. Hellier advocated the excision of the tubes by abdominal section when in such cases hæmatosalpinx was also present.—Mr. H. LITTLEWOOD, Dr. JAMES BRAITHWAITE, Dr. E. WARD, Dr. E. O. CROFT, and Mr. C. J. WRIGHT took part in the discussion and Dr. HELLIER replied.

Mr. BASIL HALL (Bradford) read a paper on Inflammatory Conditions of the Colon associated with Septic Abdominal Disease. He recorded three cases in which he had observed a train of symptoms of an unusual character. The chief features of the cases were great distension of the ascending and transverse colon, accompanied by violent, irregular, and painful peristalsis. There was no diarrhœa but the bowel was totally unable to empty its contents. There was no blood in the stools but very large quantities of mucus were evacuated after gravitation enemata. Flatus was usually passed in large quantities after a hypodermic injection of morphia had been given, suggesting that the condition might be one of spasm in the left colon. The descending colon never became greatly distended but was acutely tender throughout. The only treatment from which benefit had been derived was gravitation enemata of oil emulsion with occasional injections of morphia.—Mr. B. G. A. MOYNIHAN, Mr. J. W. DRAPER, Dr. T. CHURTON, Mr. LITTLEWOOD, Dr. W. EDGECOMBE, and Mr LAWFORD KNAGGS joined in the discussion and Mr. HALL replied.

Dr. C. OLDFIELD described three cases of Acute Parenchymatous Glossitis. In the first case the patient, aged 39 years, complained that he was unable to swallow solids because of pain in the throat. Six weeks previously he had had a sore-throat and had not been able to swallow solids from then to the date of being seen. When he was first seen there was no enlargement of the tongue, but there was some tenderness which prevented a view of the pharynx being obtained. On the third day the tongue began to swell; there were fulness in the submaxillary region, pain, and a copious secretion of mucus in the throat. Even liquids could not be swallowed. On the fifth day the tongue protruded far out of the mouth and there was great submaxillary swelling. Breathing was difficult because of the mucus in the throat. On the sixth day ether was given with great difficulty. Only a partial anæsthesia was obtained, but sufficient to allow the mouth to be forced more widely open with a gag, and an incision to be made into the tongue, letting out offensive, dirty, watery pus in considerable quantity and under great pressure. Recovery was rapid. The second case was that of a man, aged 40 years. The illness began with a rigor during the night and when the patient was seen on the next morning he had great pain in the throat and was unable to swallow. The uvula was very œdematous and enlarged. The tongue and the tonsils were normal. During the day the tongue began to swell and by the evening of the third day it was very large, forcing open the mouth and projecting through it. Swallowing was impossible, but the breathing was easy. Submaxillary swelling was not so marked in this case as it was in the case which had been described. During the night the swelling of the tongue went down and by noon of the fourth day that organ was of about its natural size. There had been no escape of pus observed. The uvula was still enlarged and it was covered with dirty white membrane on the sides and on the posterior surface. A swab was taken but Dr. E. F Trevelyan reported that diphtheria bacilli were not found in it. On the fifth day the temperature went up to 104° F. and signs of acute lobar pneumonia developed. This condition ran an ordinary course and the patient convalesced quickly. In the third case the patient, a man, aged 31 years, had had an acute tonsillitis seven days previously to the onset of the affection of the tongue. In this case also there was a rigor at the commencement of the illness, and in the course of five hours the tongue swelled so as to completely fill the mouth and to prevent swallowing. On the tip of the tongue was observed a small ulcer which had been caused by a cut from tacks which he placed in his mouth while following his employment—that of a cobbler—and from this the swelling had commenced and had spread. On the third day the swelling disappeared almost as quickly as it had appeared, no escape of pus being observed. The nature of the last case was obviously a cellulitis of the tongue and the others were most probably of the same character. In the second case the disease appeared first in the uvula and it was probably there that infection took place. The long duration of throat symptoms prior to the development of the swelling of the tongue pointed to some ulcerative condition there, most probably in the lingual tonsil. Considering how common were wounds and ulcers of the tongue it was remarkable that the disease of acute parenchymatous glossitis was so rare; especially might they expect to find it more frequently in the foul ulcerative mouths of certain diseases.—Dr. CHURTON, Dr. E. F. TREVELYAN, Dr. SANDERSON LONG, and Dr. A. BRONNER took part in the discussion and Mr. OLDFIELD replied.

Among the cases, pathological specimens, &c., shown were the following:—

Dr. CHURTON: A girl, aged 18 years, with Optic Neuritis in the Left Eye with a history of influenzal meningitis commencing with aphasia.

Mr. H. SECKER WALKER: 1. A case of Chronic Mastoid Disease operated upon by Ballance's method. The primary operation, which was performed a month ago, was followed a week later by the epithelial grafting operation and in a fortnight the whole surface was sound and dry. 2. A Diagrammatic Model to illustrate the Various Forms of Astigmatism.

Mr. C. J. WRIGHT and Mr. W. THOMPSON: Two specimens of Fibroma Removed from the Vagina.

Dr. A. MANTLE (Halifax): (1) Six cases of Raynaud's disease; and (2) two specimens of Osteo-sarcoma of the Ilium, causing Sciatica, with Secondary Deposits in the Lung.

Mr. T. R. JESSOP: (1) Uterine Myoma removed by Abdominal Hysterectomy; (2) Uterine Myoma, combined with Cervical Carcinoma and Purulent Endometritis, removed by Vaginal Hysterectomy; (3) Uterine Carcinoma removed by Vaginal Hysterectomy; and (4) Tumour (? sarcoma) of the Kidney presenting Difficulties in Diagnosis.

Mr. PRIESTLEY LEECH (Halifax): Skiagrams of Sarcoma of the Femur, Spontaneous Fracture of the Femur from New Growth, and showing Callus in the attempt to Repair.

Mr. LITTLEWOOD: (1) Hysterectomy for Hæmatometra with Suppurating Ovarian Cyst (patient and specimen); (2) large Stone removed from Common Bile Duct and another from the Gall-bladder from a woman suffering for 18 months with intense jaundice (patient and specimen); and (3) Malignant Disease of the Gall-bladder removed with Wedge-shape Portion of the Liver and a large Stone from the Duodenal Orifice of the Common Duct (specimen).

Dr A. G. BARRS: (1) Spastic Paraplegia due to Measles; and (2) grave Nervous Disease due to Measles.

Dr. WARD: (1) Cyst of the Fibula; (2) Uterine Tumour with Hæmato-salpinges; (3) Tuberculous Disease of the Hip-joint with complete Separation of the Epiphysis; and (4) Sarcoma of the Abdominal Wall.

Mr. G. MILLHOUSE and Mr. G. P. ANNING: (1) Pulsating submaxillary tumour (facial aneurysm?) associated with Undue Pulsation of the Subclavian Artery on the same side; and (2) Circumscribed Scleroderma of the Infra-orbital Region.

Mr. MOYNIHAN: (1) Growth of Sigmoid removed from a Congenital Hernia of the Sigmoid Flexure; (2) two examples of Complete Excision of the Umbilical Epiploceles (Condemin's method); (3) Pudendal Hernia, with Vaginal Cyst; (4) an example of Gangrenous Meckel's Diverticulum, causing Acute Obstruction; (5) two Gall-stones removed from Cystic Ducts, one stone removed from the common bile duct; and (6) Arterio-venous Aneurysm of the Popliteal Space the result of a Mauser Bullet-wound received at Spion Kop.

Mr. P. J. CAMMIDGE: Cast of a large Femoral Hernia.

Dr. T. WARDROP GRIFFITH: (1) A Cardiac Lesion for Diagnosis; (2) Post-hemiplegic Mobile Spasm of the Choreic Type; and (3) (with Dr. C. M. CHADWICK) Secondary Carcinoma of the Liver, with Terminal Tuberculosis.

Mr. LAWFORD KNAGGS: (1) Sarcoma of the Clavicle; and (2) four Malignant Pustules (Anthrax) from the same patient.

Mr. THOMPSON: Two specimens of Multiple Myomata of the Uterus removed by Kelly's Method of Hysteromyomectomy.

Mr. BASIL HALL (Bradford): Malignant Intussusception removed by the Sacral Route.

Dr. TREVELYAN: A case of Post-diphtheritic Debility in which the knee-jerks were absent six months after the attack.

Mr. MAYO ROBSON: Case of Coxa Vara (patient shown).

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Open-air Treatment of Phthisis.

A MEETING of this section was held on Nov. 16th, Sir CHRISTOPHER NIXON, the President, being in the chair.

Dr. F. HOWARD SINCLAIR gave a short account of his experience of two years of Open-air Treatment of Phthisis in the Forster-green Hospital, Belfast, and in the Rostrevor Sanatorium. The internal administration of antiseptics he found of little value. In selected non-febrile cases without marked physical signs good results had been obtained from tuberculin. Tuberculin was also used in the Adirondacks Sanatorium in America. Shelters and verandahs were used in wet or stormy weather, though when possible patients remained in the open up till 8.30 P.M. Electric light for this purpose was necessary. All reading and writing were done outside, the use of sitting-rooms being interdicted. It was most necessary that a sanatorium should be built for that special purpose, as no ordinary dwelling could be successfully adapted. Shelter by trees as well as local formation of country seemed to be one of the most essential features of a site. In exposed situations it became almost impossible to keep the windows open. Proximity to centres of population for obvious reasons was very objectionable. The greater the number of cases one had to deal with the more did the sanatorium physician see the absurdity of treating every case by one fixed rule. Much of the success depended on the rational allotment of rest, exercise, and dietary. Gain in weight was not always accompanied by lung improvement. Administration of large quantities of milk might for a time make up for the refusal to eat solid food. Patients must be made to understand that tuberculous sputum was a carrier of infection and that it was a means both of self-reinfection and of communicating the disease to other persons. Cremation was the most satisfactory method of disposing of sputum. Of all known methods of treatment of phthisis the hygienic, "open-air," or sanatorium system was undoubtedly the best.

Dr. J. F. O'CARROLL said that with his experience of Newcastle (co. Wicklow) Hospital he was strongly in favour of the open-air treatment, but care should be taken not to overdo it. For instance, a highly febrile patient was not fit for such methods.

Dr. E. J. MCWEENEY said it was a common belief that when the sputum became small in quantity, and that when the case had obviously improved, the infectivity of the sputum was diminishing and the number of bacilli in it was small. Recently he had a striking example of the opposite state, when he found that the scanty sputum of a patient who had gained in weight and improved in every way was loaded with bacilli. He ventured to plead for the continuance of the tuberculin treatment, not in its original form where it was considered necessary to produce violent constitutional disturbance, but in small doses, continued for a fortnight at a time with intervals. He did not advocate it from clinical experience, but he had read most carefully worked-out accounts of the effects of this treatment of patients in Germany, and he was convinced that important results could be achieved by it.

Sir J. W. MOORE said that in this discussion no one had mentioned the word "sunlight," and sunlight played a part by no means second to that of fresh air.

Dr. A. R PARSONS agreed that as an indication of improvement a gain in weight was *per se* of very little value and at Newcastle hospital they found that the very worst cases often gained greatly in weight. With regard to the tuberculin treatment which had been referred to he did not personally hope for very much from it.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 6th, Dr. Duncan Burgess being in the chair.—Dr. J. W. Martin showed a specimen of Pyosalpinx and read notes of a case of Membranous Dysmenorrhœa associated with Cystic Ovaries and Retroversion of the Uterus. The ovaries were removed and the uterus was fastened by the pedicle of the left broad ligament into the lower portion of the abdominal wound.—Mr. R. J. Pye-Smith showed: 1. A case of Bilateral Coxa Vara in a boy, aged four years, which he had shown in October, 1899. There was marked improvement in gait and in abduction of the thighs. The chief treatment had been passive movements with short periods of recumbency and exercises. 2. A case of Laparo-pylephleb-anastomosis in a girl, aged 19 years, which he had shown in March last. Since then the ascites had entirely disappeared and the general health was good. It was now 13 months since the operation. 3. A case of Regeneration of the Tibia in a girl, aged nine years, after removal of the entire diaphysis for acute infective periostitis and osteomyelitis. The operation was performed in May last on the sixth day of the disease when the shaft of the bone was found to be bathed in pus. The wound was kept open for 10 days and was then closed. A skiagram showed the presence of a good new bone and there was no noticeable deformity, the ankle and the knee were freely moveable, and locomotion was good, though at present the child was wearing an iron support. 4. A case of Moveable Knee-joint after complete Arthrectomy for Tuberculous Disease in a girl, aged seven years The synovial membrane and semilunar cartilages had been removed by Kocher's method in February last. There was but little deformity and the movements of the joints were almost perfect.—Dr. A. W. Cuff showed a case of Congenital Elephantiasis.—Dr. Arthur Hall showed a case of Lymphatic Leukæmia of 10 months' duration in an elderly man.—Dr. Hall also alluded briefly to two unusual cases of Status Epilepticus which had come under his notice in the Sheffield Royal Hospital during the previous week. In one patient, a middle-aged woman, who had never had a fit of any kind before and who was an in-patient for some gastric trouble, the fits succeeded each other with great rapidity and the patient died within three days. At the necropsy nothing was found in any organ to account for the fits. In the second case, that of a middle-aged man, the patient was found unconscious in the street and after admission to the hospital he had a series of epileptic fits following each other at short intervals for the next 24 hours. He became rather dazed for a day or two and afterwards completely recovered. In this case the patient had never had a fit before.—Mr. S. Snell exhibited the following: 1. A girl, aged 13 years, with Chancre on the Inner Surface of the Upper Eyelid. 2 A case of Rupture of the Choroid. 3. A case of Foreign Body (a piece of steel) embedded in the Retina. The date of the injury was in April last. The eye still retained good sight. 4 A case of Recovery from Sympathetic Ophthalmitis in a boy, aged 10 years. The exciting eye retained fair vision and in the sympathising eye after three recurrences vision was normal. 5. A case of Cellulitis of the Orbit in a girl, aged nine years. It occurred after a blow nine days previous to admission to hospital. Two days later, on making an incision to evacuate the pus, a small sequestrum was removed. Recovery was rapid and complete.—Mr. Snell also exhibited a large number of lantern slides of photographs of ophthalmic cases. He arranged them as far as possible in groups. Among them was a case of Double Anophthalmos, and he exhibited with this four other cases of Anophthalmos associated with Congenital Cyst in the Eyelids; there were three instances of Traumatic Enophthalmos. Various photographs illustrating causes producing protrusion of the eye were shown. One case was especially interesting as, in consequence of a fall downstairs, injury had been inflicted on the left fronto-temporal region causing apparently a fracture involving both orbits. The left optic nerve was so injured that complete blindness had resulted, and in the right eye there had been orbital aneurysm and the common carotid artery had been tied. In connexion with this case photographs were shown of injuries to the anterior part of the head from cases under the care of Mr. Snell in which blindness had been occasioned through the fracture involving the optic foramen. Mr. Snell mentioned that he had recorded in the Transactions of the Ophthalmological Society of the United Kingdom 18 instances of this sort which had come under his observation, but he had had five additional cases recently.

MIDLAND MEDICAL SOCIETY. — The second ordinary meeting of this society was held on Nov. 28th, at the Birmingham Medical Institute, Mr. Jordan Lloyd, the President, being in the chair.—Mr. J. G. Emanuel was elected a member of the society.—Mr. W. F. Haslam showed a woman, aged 46 years, suffering from Charcot's Disease. She had always had good health except for the fact that for the last five or six years she had had pains in both legs at irregular intervals. Ten months ago she twisted her right knee in getting into a cart; but she was able to go on with her work on that day. On the following day the knee was greatly swelled but there was very little pain. She kept about for two weeks, but then, owing to the weakness of her knee, she rested in bed for three weeks. The swelling disappeared to a great extent, but she could not trust herself to bear much weight on the knee, as it felt as if it would give way. Her condition on admission was as follows. She walked with difficulty, owing to the weakness of the right knee, but there was very little pain in it. This knee was two and a half inches more in circumference than the sound one. There was swelling of the synovial membrane, but very little fluid was present. The temperature of the knee was increased Flexion was very limited owing to locking of the bones but the joint otherwise was very loose and there was considerable hyperextension and lateral movement There was slight thickening about the lower end of the femur The patient could stand with her eyes shut There were no gastric crises Tactile and heat and cold sensations were normal and the pupils reacted to light and accommodation The patient had no trouble with her bladder or rectum The knee jerk on the left was absent There were shooting pains in the legs at times The x rays showed (1) very marked displacement of the tibia forwards and outwards, (2) slight thickening of the lower end of the femur, and (3) considerable erosion of the condyles of the femur and some erosion of the head of the tibia —Dr A S Underhill showed a Uterus with a Lacerated Cervix and Vagina The patient was a multipara, aged 34 years On Oct 4th, 1900, being in labour, she sent for a midwife In about seven hours after much difficulty the head and shoulders were born, but as delivery could not be completed a medical man was sent for who used some traction and, not feeling certain as to the condition, advised her removal to the Guest Hospital, Dudley On admission the head and thorax were protruding from the vulva, and the upper cervical and mid dorsal vertebræ were separated so that the parts were only held together by skin The vagina was completely blocked by a large fœtal abdomen palpably full of cysts Embryotomy was completed by emptying several cysts No force was used and the fœtus was easily expelled The placenta came away directly afterwards Hæmorrhage was slight and the uterus contracted firmly A full dose of ergot was given and the patient was put back to bed Four hours afterwards the house surgeon found her blanched, with a feeble, running pulse restless, and only partially conscious There was very little bleeding externally Her abdomen now contained two swellings, the well defined, firmly contracted uterus, and by its side a deep seated but less distinct swelling which was crepitant on palpation, reaching well above the umbilicus She died shortly after in a state of collapse Post mortem examination showed a deep laceration through the whole thickness of the cervix and the adjacent wall of the vagina The peritoneal cavity was not opened, but the peritoneum was stripped from the posterior wall of the abdomen to the left kidney, forming a large cavity filled with blood clot and causing the second swelling noticed before death A fairly large vessel was found in the lacerated cervix, which had evidently been bleeding, and caused the stripping up of the peritoneum and the consequent death from hæmorrhage —Dr Underhill also showed a specimen of Double Hydronephrosis with Sacculated Ureters, a large Thickened Bladder, and a Stricture close to the Membranous Portion of the Urethra It was taken from a fœtus born at full term but dead There were other abnormalities about the fœtus a double harelip, cleft-palate an inter ventricular foramen, a supernumerary finger on each hand, and a supernumerary toe on each foot —Mr William Thomas showed specimens of the Clip Sutures advocated by Dr Paul Michel —Mr G Heaton read a paper on the Prognosis and Treatment of Hernia in Childhood

GLASGOW SOUTHERN MEDICAL SOCIETY – An extraordinary meeting of this society was held on Dec 14th, Dr William Watson, the President, being in the chair Owing to the crowded attendance through the importance of the subject—Consideration of the Action of the General Medical Council in their Recent Decision respecting the Sale of Drugs and Poisons by Unqualified Drug Assistants—it was found necessary to leave the usual meeting-place and to secure a larger hall —The President, in introducing the business, explained the reason of their special meeting and drew attention to the various points in the trial of the Airdrie practitioner before the General Medical Council He asked for an expression of opinion by those present on the very serious issues involved —An interesting discussion followed, in which the feeling was expressed that a very serious hardship would fall to the lot of general practitioners should the decision of the General Medical Council be maintained In the opinion of some the General Medical Council had no *locus standi* in the question at issue, inasmuch as there had been no breach of the Pharmacy Act, and in their opinion the offence with which the practitioner had been charged could not by any reason be considered under the category of "infamous conduct in any professional respect" whatever. The open and continued hostility of the Pharmaceutical Society against the general medical practitioner was bitterly commented on by various speakers It was common knowledge that chemists and druggists themselves were guilty of the same offence, for they habitually employed unqualified assistants who dispensed and sold drugs and poisons The Pharmaceutical Society, it was held, should see that those whom they represented kept their own houses in order before interfering with the general practitioner Various suggestions were made in the course of the discussion as to the best methods of conserving the interests of medical men A motion was proposed that this could best be attained at the present juncture by the formation of a Medical Defence Union, but owing to the lateness of the hour and the desire for further discussion the meeting was adjourned until an early date

LIVERPOOL MEDICAL INSTITUTION —The second meeting of the Pathological and Microscopical section of this society was held in the theatre on Dec 13th, Dr J H. Abram being in the chair —Dr W Alexander and Mr J E Dimond showed a Cervical Rib removed by Operation, Scirrhus of Mamma, and a Malignant Uterus —Mr Douglas Crawford showed a specimen of Multiple Sarcomata from a female, aged 30 years Growths were present in the upper end of the right humerus and the right half of the lower jaw . The upper third of the humerus and the right half of the mandible were removed and there was no recurrence six months later The growths were both of the spindle celled variety —Dr F H Barendt showed a section of Ephelis *ab igne* with pigment cells in the derma, also pigmented skin due to arsenicated beer, the pigment being in the deeper stratum of the Malpighian layer —Mr F T Paul showed an Adenoma of the Kidney which he had removed during life, also a Vermiform Appendix very much enlarged —Dr R J M Buchanan showed Sections of a small Adenoma of the Kidney discovered post mortem in a patient who had died from Scirrhous Carcinoma of the Pylorus —Mr G P Newbolt showed a Testis which he had removed with a Cyst which had totally destroyed the Epididymis The cyst had a thick wall and contained straw coloured fluid There was also a hydrocele of the tunica vaginalis —Dr W Blair Bell showed a specimen of Carcinoma which he had removed from a male breast —The specimens were discussed by Dr Abram, Mr Paul Mr Newbolt, and Mr K W Monsarrat — Dr W B Warrington and Dr J E Dutton read a note on the Course of the Optic Tracts studied from a case of Unilateral Optic Atrophy The note was illustrated by numerous microscopic sections, drawings, and lantern slides —A discussion followed in which Dr Abram, Dr. A S F Grunbaum, and Dr John Hay took part, and Dr Warrington replied.

BOURNEMOUTH MEDICAL SOCIETY —A special meeting of this society was held on Dec 14th to consider a report from the committee on the possibility of providing better accommodation for the society and its library The report, which had been printed and circulated, was taken as read After some discussion it was adopted with only one dissentient —Dr F O Bottomley read a paper on Some Sensory Affections of the Upper Extremity He said that when working in the out patient room of a London hospital he was struck by the number of patients complaining of one or more of the following symptoms affecting the arms—viz , pain, loss of power, numbness, tingling or coldness He had made brief notes of 27 such cases He gave details of these, from which it appeared that the majority were women, the average age being 44 years Both arms were affected in 10 patients, the left arm alone in nine, and the right alone in eight The duration of the symptoms varied from a few weeks to months He considered whether there was any lesion in the arm to account for the symptoms, such as neuritis, or whether the affection was functional or hysterical or caused by overwork or strain or whether the pain was a referred pain or due to some disturbance of the circulation in the limb such as a vaso constriction Having discussed each of these possible explanations he thought that the symptoms were entirely subjective and that they were referred from some other part in the same way as pain from a decayed tooth is frequently referred to the temple He gave reasons in support of this view such as the referred pain and other sensations due to flatulence or indigestion — Dr A Kinsey Morgan, sen , read a paper on the Modern Treatment of Phthisis

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on Dec. 5th.—Mr. R. C. Chicken read a paper on the By-ways of Appendicitis. Dealing first with the symptoms of appendicitis, he affirmed that they were very illusive; all might be present and yet no appendicitis be found. He cited, as examples which had been known to simulate the condition, typhoid fever, subdiaphragmatic abscess, psoas abscess, acute intestinal obstruction, tumours in connexion with uterine appendages, and other pelvic tumours. The actual condition could only be cleared up by laparotomy. He then discussed the points for incision, pointing out that the painful spot was only valuable as a diagnostic sign before suppuration, and only rarely should the top of the incision be above a line drawn from the umbilicus to the superior iliac spine, extending from the edge of the rectus outwards. Specimens illustrating his paper were shown: (1) Excised Sloughing Cæcum; (2) Malignant Stricture of the Sigmoid Flexure; (3) Malignant Stricture of the Hepatic Flexure of the Colon; and (4) Tuberculous Tumour of the Cæcum, simulating appendicitis, and enlarged mesenteric glands. The second and third specimens exemplified the fact that stricture of the intestine might exist in a chronic form without evidence of obstruction but only of constipation. The lumen in each case was of the size of a No. 16 catheter.—Dr. H. Handford showed a microscopic section of the Thyroid Gland in which no gland epithelium was left. The specimen was from a man who was the subject of myxœdema and who was shown to the society in February, 1899.

Bristol Medico-Chirurgical Society.—A meeting of this society was held in University College, Bristol, on Dec. 12th, Dr. D. S. Davies, the President, being in the chair.—It was proposed by the President, seconded by Dr. B. M. H. Rogers, and carried:—

> That the cordial thanks of the society be accorded to Mr. Paul Bush for the most interesting series of lantern slides that he showed at the close of the last meeting, illustrating hospital and other scenes he had taken during the Boer war.

—Mr. A. W. Prichard read notes on a curious case of Hypertrophy of the Hand, the patient being shown as well as skiagrams and photographs.—Dr. J. Michell Clarke and Mr. W. Roger Williams discussed the paper.—Dr. Michell Clarke showed a patient with Muscular Atrophy.—Dr. T. Fisher showed a patient with Patent Ductus Arteriosus.—Dr. Clarke and Dr. E. H. E. Stack remarked on the case.—Dr. J. O. Symes showed a microscopic specimen of Leukæmic Blood.—Dr. A. J. Harrison and Mr. Roger Williams commented on the case.—Mr. Roger Williams read a paper on Medical Science in the Nineteenth Century.—Dr. J. Lacey Firth read notes on a case of Bilocular Hydrocele.—Mr. Munro Smith and Mr. J. Paul Bush spoke on the condition.

Southport Medical Society.—The second meeting of the present session was held on Nov. 14th, Dr. R. Harris being in the chair.—Four new members were duly elected.—Mr. S. Backwell Fenn gave a short history of the case of Obliterative Endarteritis, probably syphilitic, shown at the last meeting.—Mr. F. J. Baildon showed a case of Disarticulation at the Shoulder-joint.—Dr. A. Storrs read a very interesting paper on Vaccination, which provoked an animated discussion, complaints as to the unreliability of glycerinated calf lymph being numerous.—The third meeting was held on Dec. 12th, Dr. Harris being in the chair.—Two new members were duly elected.—The President raised the question of the Infrequency of Medical Evidence at Inquests in the District, and after some discussion a deputation was unanimously appointed to wait upon the coroner and to lay the views of the profession before him.—Mr. G. Reinhardt Anderson read an able paper upon Appendicitis and showed specimens of diseased appendices removed by him. Rules for treatment and for operative interference were also laid down.—A discussion followed.

Glasgow Pathological and Clinical Society.—A meeting of this society was held on Dec. 10th, Mr. H. E. Clark, the President, being in the chair.—Dr. James Carslaw showed (1) two patients who suffered respectively from Peripheral Neuritis as a Complication of Enteric Fever and (2) Hemiplegia occurring in the course of Enteric Fever but probably the Result of Mitral Stenosis.—Professor Robert Muir gave a microscopical and lantern demonstration of some of the Bacteriological Features of Bubonic Plague.—Dr. George T. Beatson showed a series of skiagrams of Tumours connected with Bone.—Dr. A. W. Russell showed a Uterus the seat of Multiple Myomata. There had been encysted hæmorrhage into the left ovary.—Dr. Munro Kerr showed as a fresh specimen the Lungs and Kidneys from a case in which Embolism of the Pulmonary Artery had occurred 14 days after labour.

Rochdale and District Medical Society.—At a meeting of this society held on Dec. 6th Mr. G. W. Malim read a paper on Pernicious Anæmia and mentioned that he had recently had three cases in three contiguous houses. He supported the theory that the excessive destruction of coloured corpuscles which had been shown to occur was due to the absorption of a poison by the gastro-intestinal tract. He also gave some useful hints on treatment, especially as regards diet.—Mr. W. Pooley mentioned a case which had occurred in his practice. A woman died from pernicious anæmia and shortly afterwards her husband died from the same disease.—Dr. W. E. Jameson, Dr. D. Richmond, Mr. J. Chadwick, Mr. W. Stanwell, Dr. W. J. Kerr, and Dr. A. Wallace also took part in the discussion which followed the paper.

Reviews and Notices of Books.

Thomas Henry Huxley: a Sketch of his Life and Work. By P. CHALMERS MITCHELL, M.A. OXON. New York and London: G. P. Putnam's Sons. 1900. Pp. ix.-297. Price 5s.

APPEARING so soon after the two large volumes of biography by Mr. L. Huxley, which we noticed in THE LANCET of Nov. 17th, there might at first sight seem to be no need of the present volume. Mr. Mitchell has, however, treated the subject-matter from an entirely different point of view, and instead of providing us with a record of daily life and occupations has picked out the main thread of Huxley's contributions to science and to contemporary thought for continuous presentment. From the few pages which make up this volume it is possible to get a clear grasp of the main achievements of a remarkable man, while the account is clothed only with just sufficient extrinsic matter to attract the attention and to explain the external circumstances which had influence upon his doings and writings. It is significant and not at all gratifying to find that Mr. Mitchell feels himself obliged—and we admit that he is obliged—to emphasise more than once the position of Huxley as a great original explorer in the domain of comparative anatomy. Popular estimation of that eminent anatomist was well expressed to us once by a clergyman who inquired "Why is he called Professor Huxley? What is he professor of?" The public do not read the Philosophical Transactions or the Proceedings of the Zoological Society; but they do read the daily papers and are thus apt to gauge the eminence of a man by the number of times he appears therein. It is hardly too much to say that the professor's extensive reputation was nearly entirely due to his advocacy of, or attacks upon, commonplace matters understanded of the people. He unfortunately bulks much more largely as an objector to the Gadarene swine and as the inventor of the phrase "Corybantic Christianity" than as the exponent of the vertebrate skull and as the comparer of the two-layered condition of the embryos of the higher animals to the adult hydrozoon. It is urged that Huxley advantaged science greatly by his continual presence in the arena before the general public, but we are not at all so convinced of this For the possibilities which he showed have led men of vastly inferior achievements, but gifted in the use of the pen or the tongue, to pose as exponents where they should be humble learners.

Mr. Mitchell justly points out that one marked feature of the contributions of Huxley to zoological science is their extreme exactness; there is but little to correct in his statements; and when it is reflected how poor were the instruments and methods of displaying minute structure at the time when he was chiefly engaged in work the wonder at these achievements grows. To examine a medusa through a microscope "lashed to the mizen mast" and to deduce therefrom truly epoch-making generalisations is a feat which requires no disputes with Owens and Wilberforces to enhance it. Mr. Mitchell devotes a page or two to the important subject of geographical distribution. It is interesting to note that current opinion at the present moment is perhaps rather more strongly in favour of the views expressed by Huxley in his celebrated paper upon the anatomy and range of the Gallinaceous birds than it was at the time. "There has been recently," writes Mr. Mitchell, "a recurrence to Huxley's suggested union of South America and Australia." We are not, however, quite in accord with Mr. Mitchell in his advocacy of this view so far as concerns details. The important fact of the occurrence of a diprotodont marsupial, first named by Mr. R. Tomes "hyracodon," in South America, would rather be interpreted on our view by the theory that the two divisions of the marsupials had already arisen in Europe and North America before the spread of the race to South America on the one hand and to Australia on the other. Moreover, the connexion of South America with Australia was, we are disposed to think, indirect and through New Zealand, which was itself connected with Queensland. This view of the matter seems to be supported by certain freshwater fishes, and above all by the range of one or two genera of earthworms, creatures impatient of salt water and thus dependent upon a land connexion for possibilities of migration.

This, however, is not the place where these matters can be debated at length. It remains only to say that the writing of this appreciation of Huxley has fallen into precisely the right kind of hands; for Mr. Mitchell is competent by his own investigations into comparative anatomy to treat with a proper sense of proportion the vast amount of discovery connected with the name of Huxley, while he has the requisite literary skill to present his statement in such a way as to appeal to the reader.

Handbook of Practical Botany for the Botanical Laboratory and Private Student. By Dr. E. STRASBURGER, Professor of Botany in the University of Bonn. Translated and Edited from the German with many additional notes by W. HILLHOUSE, M.A., F.L.S., Professor of Botany and Vegetable Physiology in the University of Birmingham. Fifth edition. Rewritten and enlarged. London: Swan Sonnenschein and Co., Limited. 1900. Pp. xxxii.-519. Price 10*s*. 6*d*.

THE fact that this work has reached a fifth edition must be a source of gratification to all concerned. As is well known the volume before us is a translation of Dr. Strasburger's "Das Botanische Praktikum," which is one of the best handbooks for certain branches of practical botany—namely, anatomy and histology—which we possess. From the preface it may be gathered that this edition has been practically rewritten, and also that a certain number of new figures have been added.

It is a matter of some little difficulty to review a book which has been used for a considerable time and hence is so well known. There are, however, a few points to which attention may be drawn. In Chapter XXVII. the fertilisation of *Picea* is described and also the behaviour of the nucleus of the egg after fertilisation has been effected; on page 376 it may be read that "The next stages take the embryo nucleus into the end of the oöspore remote from the neck, where, by repeated bipartition, it forms four nuclei lying in the same plane." Judging from the most recent research into the fertilisation of this class of plants, this statement is not quite correct. For instance, V. H. Blackman makes the following remarks. "It is clear from my observations that though a definite fertilised nucleus hardly exists as such, the first segmentation spindle appears in the position formerly occupied by the female nucleus. The two daughter nuclei themselves also undergo division before they begin to wander down to the base of the egg." Dixon also ascertained that the fertilised nucleus divided in the centre of the oöspore.

As regards another point, we should like to suggest that Professor Hillhouse would have done well to have added an alternative plant for the study of fertilisation in sea weeds. The types taken are *Fucus platycarpus* and *F. vesiculosus*. Although the fertilisation in these two plants is extremely interesting, still there is another in which the process is still more so. We refer to *Halidrys*. Fertilisation in this plant is very easily observed, and as to its interest the following quotation from Farmer and Williams will answer. The male elements, as is well known, attach themselves to the egg and cause it to rotate by the movements of their cilia. "Suddenly the antherozoids are seen to leave the egg like a crowd of startled birds or else they become quiescent, and these phenomena are immediately followed by a great change in the egg itself, which becomes warty and covered with conical projections. ...... We consider it as certain that the flight of the supernumerary antherozoids marks the moment of actual fertilisation and it seems only possible to interpret the events outside the egg as the result of an excretion from it of some substance which not only exerts on the surrounding antherozoids a negative chemiotactic but also a directly injurious effect, for a number of dead sperms may be seen around the fertilised egg."

In the portions dealing with the fertilisation of angiosperms we do not notice any mention made regarding the recent discoveries of the triple fusion of nuclei, the two polar with the second generative nucleus of the pollen-tube, to form the endosperm (or definitive) nucleus of the embryo sac. It is to be borne in mind, however, that in the types described this phenomenon has not yet been observed excepting in the case of *Monotropa*. Although these discoveries were not made till after the publication of the third edition of Dr. Strasburger's "Das Botanische Praktikum," of which full use has been made in this edition of the translation, still the facts are of sufficient importance to warrant mention. These remarks do not apply to the case of *Monotropa*, for it is only quite recently—indeed, within the last month or two—that the so-called "double fertilisation" has been observed.

Excepting the above points the book is extremely good. The work is so carefully graduated and the directions as to technique are so numerous and practical that a beginner in this branch of knowledge need find but very few difficulties in this all-important side of botany. The volume is rendered more valuable by the addition of appendices which deal with English and metric weights and measures, plants and materials used for study, the preparation of, and methods of using, reagents, &c., mentioned in the text, and finally some general notes on methods and selected reagents.

The Great Boer War. By A CONAN DOYLE With Maps. London: Smith, Elder, and Co. 1900. Pp. 552, including Index. Price 7*s*. 6*d*.

THIS is a big book and requires careful reading, and, what is more, it well merits it. The author, besides having a natural and graphic style of writing which makes perusal pleasant, has approached his subject with a sense of responsibility and with an evident desire to weigh thoughtfully and impartially all he has to say. It is possible, he states with modest frankness, that a fuller knowledge may give an entirely different meaning to some of the events of the Boer war. "The occasional judgments and criticisms on which I have ventured may be founded upon error, but at least they are made without either fear or favour."

The book begins with a brief sketch of the history of the Boers and is followed by chapters descriptive of the cause of quarrel and negotiations, carrying us on to the eve of war and the battle of Talana Hill, which is characterised by the author as "a tactical victory but a strategical defeat." After that the volume is almost entirely one of military history—battles, sieges, and engagements of one sort and another—with a final chapter on some of the military lessons of the war, into which, as appertaining more especially to military critics and army reformers, we need not enter. The historical details descriptive of the state of affairs antecedent to our defeat at Majuba Hill and from that onwards until the present campaign began in earnest are lucidly and, as it seems to us, fairly set forth. It will be seen that this work has been brought out before the war has ended; for, in the face of recent occurrences and despite what Lord Roberts has told us, it cannot be said to have terminated yet.

Readers of any history of the Boer war will turn with much curiosity and interest to those sections which deal with the battles of Lombard's Kop and Nicholson's Nek, Lord Methuen's operations on the Modder, the battle of Colenso, the affair at Spion Kop, the siege of Ladysmith and its final relief, and with the advance and successful strategical operations of Lord Roberts's army. They will not be disappointed with the graphic description which the medical novelist gives of these stirring events. A great deal has been said about the want of strategical foresight and ability which characterised the earlier phases of the war, but many judgments may have to be recast and possibly, as a matter of justice, withdrawn when all is known. Dr. Conan Doyle makes it clear to us that the Boer leaders missed their opportunity by not having concentrated their efforts at the beginning of the war on the capture of the country in the direction of Durban. The fighting in Natal and the various sieges had the effect of frustrating any scheme of the kind later. In his chapters on "The Halt at Bloemfontein" and "The March on Pretoria," and in his final chapter summarising some of the military lessons of the war, the author has a good deal to say about medical matters and the epidemic outbreak of enteric fever, which, if not of an exhaustive character, is interesting and conceived in a very fair and just spirit. Probably Dr. Conan Doyle recognised that this particular subject was altogether too special to be adequately discussed in a book of this kind and so did not attempt it. Our readers will have gathered from our remarks that "The Great Boer War" is, in our opinion, an interesting and eminently readable book.

We may add that the short sketches and descriptive touches of character of many of the generals and leaders in the war which are interspersed in the volume are excellently done. It should be mentioned that the volume is illustrated by some good maps, a reference to which is of much help to the reader.

BRISTOL HOSPITAL SUNDAY FUND.—At a meeting of the committee of the Bristol Hospital Sunday Fund held on Dec 13th under the presidency of the Lord Mayor it was reported that on Hospital Sunday, Jan. 28th, 1900, collections were made in 223 places of worship, an increase of 40 as compared with the previous year. The amount received was £1383, or £125 less than in 1899 It was decided that in 1901 Jan 27th should be observed as Hospital Sunday.

THE CLIFTON CLUB.—The committee and members of the Clifton Club, Bristol, entertained Mr J. Paul Bush at dinner on Dec 13th. After dinner Mr. Bush gave a most interesting lecture on his experiences in South Africa, and his lantern slides illustrating scenes during the Boer War were much enjoyed by the company present.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 13th, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., the President, being in the chair.

The resignation of Mr. Edward Trimmer, M.A., the secretary was accepted. Mr. Trimmer's retirement will date from March, 1901, when he will have been connected with the College for 42 years. Mr. Sibert Cowell, the present assistant secretary, was appointed his successor.

The resolutions carried at the annual meeting of the Fellows and Members in November were read. In reply to the first resolution, which urged the Council to take steps to obtain representation for the Members, it was resolved to say:—

> That the Council, having fully considered the resolution moved by Dr. Herbert Snow and seconded by Mr. Joseph Smith, and carried *nem. con.*, are of opinion that it would be most undesirable to re-open the question of representation of the Members on the Council.

In reply to the second resolution, requesting the Council to take steps towards obtaining a Parliamentary inquiry into the working of the Medical Acts with a view to their amendment, it was resolved to say:—

> That the mover, Mr. George Brown, and the seconder, Dr Danford Thomas, of Resolution No II. carried at the annual meeting of Fellows and Members be requested to furnish the Council with information as to the points in regard to which they are of opinion the Medical Acts require amendment.

With regard to the third resolution, which claimed for every Member the right to receive a copy of the annual report of the Council without application, it was resolved:—

> That the annual report of the Council be sent only to those Fellows and Members who apply for it, but that to save unnecessary trouble to those who desire to receive the report regularly any Fellow or Member may, on request, have his name entered upon a standing list.

It was further resolved that the mover and seconder of the fourth resolution carried at the annual meeting of Fellows and Members be informed that the resolution had been laid before the Council. The Council also resolved to accede to the request expressed at the annual meeting, that the names of deceased Members who have died during the year should be recorded in the annual report, as in the case of the Fellows.

A report was presented from the Centenary Committee in connexion with the Guarantee Fund, by which it was shown that the cost of the centenary dinner with other expenses amounted to £798 and that £308 of this were received by the subscriptions from Fellows and Members for dinner tickets, and that the balance—namely, £490—was contributed by the guarantee fund of the members of the Council.

The SECRETARY reported the death of Professor Albert of Vienna, and of Professor Ollier of Lyons, honorary Fellows of the College, and the President was requested to address letters to the families of the two late honorary Fellows expressing the sympathy and the condolence of the Council.

The Council decided to renew for another year the recognition of Cooke's School of Anatomy, Physiology, and Operative Surgery for the performance of the extra six months' dissections required for the primary Fellowship examination.

The PRESIDENT reported that Mr. John Langton had delivered the Bradshaw Lecture on Dec. 12th and that the subject of the lecture was "The Association of Inguinal Hernia with the Descent of the Testis."—The best thanks of the Council were given to Mr. Langton for his lecture and he was requested to publish it.

The PRESIDENT informed the Council that property extending from Serle-street up to Nos. 35 and 36, Lincoln's-inn-fields had been acquired by the Crown and that it was proposed to erect on this site a building projecting beyond the general building line to within four feet of the pavement.—The President was requested to write to the First Commissioner of Works setting forth the objections to the plan and asking him to reconsider the matter.

Mrs. Henry Lee presented to the College a bust of her husband, the late Mr. Henry Lee, by Mr. Thomas Brock, R.A.—The gift was accepted by the Council with thanks.

THE LANCET.

LONDON SATURDAY, DECEMBER 22, 1900

IN no one disease is prognosis more difficult to determine than in pulmonary tuberculosis Dr ROBERT MAGUIRE in the Harveian Lectures before the Harveian Society of London which we recently published, gave a thoughtful disquisition on the several points that have to be considered by the physician before a decision can be arrived at He pointed out that a difficulty besets us even before we can approach the subject proper, and that is, to define what we understand by prognosis in each of the so called "stages" of the disease In the first stage, that of invasion we wish to attain to complete cure of the patient, an absolute arrest of the bacillary action, and a return of the lung to an entirely normal condition, though of course, the same tendency which led to the disease previously, being a tendency innate in the subject, will still exist That tendency having shown itself, perhaps being recognised for the first time on the outbreak of the lung trouble, may be combated by suitable means, but for a long period must remain with the patient When the disease has reached the second stage—according to the lecturer, "that of progress of the bacillary infection," or as it is more generally known, the "stage of softening"—arrest of the condition may still be hoped for, but if accomplished it will only be after a certain amount of damage to the lung tissue has been done—damage which is evidenced afterwards by cicatricial tissue and pleural adhesions Yet this damage may eventually give the patient no trouble if only the tendency to further attacks be kept well under control In the third stage we find total destruction of lung tissue, the result, as Dr MAGUIRE says, of bacillary action, and he maintains that the most favourable prognosis which can be made in the third stage must be vastly less favourable than that of either of the two preceding stages That a patient in the third stage of pulmonary tuberculosis is open to great danger of fresh activity cannot be doubted, but it is common medical experience that a patient who has reached the third stage has more chances of prolonged life than one in the first stage, and consequently Dr MAGUIRE'S general statement must be taken with reserve Dr MAGUIRE, however, sets forth very clearly the grounds upon which he founds a prognosis and shows that he does not make his deductions without examining his facts He takes into consideration the stage of the disease, but he also lays stress on the antecedent conditions, the nature of the physical signs, the localisation of the physical signs, and the significance of individual symptoms And he points out that if there are certain cases in which the physician does not hesitate to give an opinion, there are others which present the greatest difficulties Dr MAGUIRE draws particular attention to one class of cases in which the constitutional symptoms are out of all proportion greater than the physical signs He thinks that under such circumstances an unfavourable prognosis must be given, and he suggests the term "latent pulmonary tuberculosis" for this variety of the disease We think the term a good and explicit one, for, as he remarks, the tuberculosis itself is active enough but its pulmonary characteristic is latent And we agree that the prognosis in such cases is serious

Turning now to Dr MAGUIRE'S remarks on treatment we must speak with considerable reserve The experiments which he has described are novel and interesting, and were carried out with great care, while before attempting to treat patients he experimented upon himself Some of his experiences were apparently the reverse of pleasant He adopted the method of injecting into the veins a solution of formic aldehyde of the strength of 1 in 2000, which had been proved to be a most efficient germicide Dr. MAGUIRE was certainly bold in his resolution to employ such a medicament, but after proving on himself the strength that might be administered without danger he was justified in prescribing it for the relief of patients suffering from pulmonary tuberculosis Hitherto the use of germicides in this disease given with the idea of directly attacking the bacillus of tuberculosis in the lung, has not met with great success; indeed, the energies of physicians have been directed rather in the direction of starving out the organisms, so to speak, by rendering the tissues unsuitable for their growth, and the favourable results obtained by this means have been undoubted Naturally, if a means can be devised by which the bacilli can also be destroyed by the use of drugs which at the same time do no harm to the host, a great advance has been made Whether Dr MAGUIRE has succeeded in solving the problem remains to be proved He did not give details of the cases treated by his method but merely the summary of the results He stated that "almost every case has shown some improvement" Before expressing any definite opinion on the subject we think it well that some time should elapse so that those cases already injected may be watched, and also to enable a larger number of cases to be observed No bad results seem to have followed the injections We demur, however, to the statement that "no fear need be entertained from the entrance of a small amount of air into the veins This is an old fashioned surgical fallacy" A "small amount of air' in the vein may do no harm, but as this fortunate result depends upon what is meant by a "small amount it is better that no air should be admitted to the circulation

We publish this week a lecture delivered at the Brompton Hospital for Consumption and Diseases of the Chest by Dr ARTHUR LATHAM, physician to the hospital, the subject of which is the Tuberculosis of Early Childhood Dr LATHAM confesses that our knowledge of the etiology of pulmonary tuberculosis is not so definite as we could wish and forms an insufficient basis for the dogmatic assertions of the present day He adheres to the old established belief that predisposition—the hereditary and acquired character of the soil—is a most important factor The discovery of the tubercle bacillus promised to deal a death blow at the hereditary character of pulmonary tuberculosis, as investigations proceeded, however, it was speedily found that the bacillus itself did not explain the entire etiology and that a second etiological factor existed, the exact nature of which has not been established, and until this has been accomplished we agree with Dr. LATHAM that the hereditary factor cannot be eliminated. He further expresses his belief in the important rôle played in infantile tuberculosis by the milk-supply. This was fully proved by the investigations conducted under the instructions of the Royal Commission on Tuberculosis. Arguing from a pathological point of view Dr. LATHAM holds that in adults, in whom in the majority of cases an air infection has to be dealt with, the lungs are affected before, and more extensively than, the bronchial glands; consequently if in children the primary affection is also through the air-supply a similar condition of things should be found, whereas the opposite condition exists. That is to say, that in young children tuberculous disease of the lungs does not often occur unless the pathogenic bacilli first establish a hold on and produce more or less advanced pathological changes in, the bronchial glands. This is an interesting point and one that might have an important bearing upon treatment.

The observations of Dr. MAGUIRE and Dr. LATHAM show that investigations of pulmonary tuberculosis from every point of view are constantly being made and that a continuous fight against the disease is being waged. The British Congress on Tuberculosis which is to be held in London next year will doubtless stimulate many others to bring before the profession the results of their studies and investigations. The new century could not, from a medical point of view, open better than by registering a decided advance in our knowledge of the nature and mode of prevention of one of the most prevalent and fatal of diseases.

THE circumstances which led to the founding of the Birmingham Consultative Medical and Surgical Institution are well known to our readers, for we have explained at some length the principles upon which the institution was established, and have expressed at the same time our entire disapproval of them. The main reason asserted for its proposed existence was that there appeared to be no proper medical provision for a certain class of the population in Birmingham whose financial position, while it placed them above taking advantage of charitable institutions, was yet insufficient to allow them to pay the full fees of consulting physicians and surgeons. It was therefore suggested that an institution should be formed where the advice of "consultants" could be obtained for a fee of half a guinea; and advertisements were issued for a "consulting physician" who for a salary of £500 a year was to give his whole time to the work. The fees, of course, were to go into the exchequer of the institution. As soon as the proposal was publicly mooted a meeting of members of the medical profession in Birmingham was convened by Dr. R. SAUNDBY when resolutions condemning the project were unanimously passed. At the same time it was intimated that with the exception of a few of the senior consultants, who for obvious and proper reasons stood aside, the physicians and surgeons of the city were willing to see patients for a fee of half a guinea provided that satisfactory evidence was adduced that these patients were unable to pay the full fee. This generous offer was, however, totally disregarded, and Dr. HENRY WARD IRVINE was appointed consulting physician to the institution.

At the recent meeting of the General Medical Council Dr. IRVINE was summoned to answer the charge "that he accepted the office of consulting physician to the Consultative Medical and Surgical Institution, Birmingham, at a salary, and approved or acquiesced in the extensive advertisements issued by that institution by posters exhibited in the various manufactories, trading establishments, and mercantile offices of the city, by advertisements in the daily press, and by lithographed letters and printed pamphlets, widely circulated, setting forth conspicuously his name and medical qualifications, and referring to his special ability as a general consulting practitioner, and soliciting and inviting the public to consult him at a reduced fee." The "complainant" nominally was Dr. SAUNDBY, but really the medical staffs of the Queen's Hospital and the General Hospital, Birmingham, of whom Dr. SAUNDBY was the mouthpiece. The case was conducted on behalf of the medical staffs by the Medical Defence Union, whose council once again demonstrated the excellent service that they are prepared to render not only to their own members but, when the occasion warrants it, to the medical profession generally. Dr. A. G. BATEMAN, the general secretary to the Union, conducted the case on behalf of his council, while Dr. IRVINE attended with Mr. FREEMAN, Q.C. Dr. BATEMAN pointed out the extent to which the advertisements had been circulated, and produced a copy of a broadsheet, containing Dr. IRVINE'S name and qualifications, the hours of consultation, and fees, which had been distributed to restaurants, mercantile offices, factories, and board schools. He urged that there could be no question that Dr. IRVINE'S conduct was "infamous in a professional respect," and that the fact that this advertising was done under the ægis of an institution managed by laymen did not alter the gravity of the professional offence and could not be held to excuse or to palliate such conduct. Mr. FREEMAN argued that the institution had been set on foot by public-spirited citizens with no view whatever to their own profit. He called Mr. ARTHUR CHAMBERLAIN, who maintained that the institution was a philanthropic undertaking which the founders hoped would essentially become self-supporting, but that it could not be called a charity, because one of the objects which the management had in view was the preservation of the self-respect of persons who ought not to seek aid from a hospital but were yet in need of some higher advice than they would get from their "street doctor." This distinction between a "philanthropic" and "charitable" establishment we find it a little difficult to appreciate, and we most strongly protest against the use of the term "street doctor." Mr. ARTHUR CHAMBERLAIN evidently meant by this phrase to belittle the position and services of the Birmingham general practitioners, a course which will not commend itself to the public any more than it does to us. For the public knows well the sterling as well as generous nature of the work done by our profession, and may fail to see much philanthropy in the offer of the institution to do, through Dr. IRVINE'S single hands, what the genuine consultants of Birmingham are willing to do for the same money but with more experience and more varied knowledge

Dr BATEMAN drew attention to the fact that there was no wage-limit specified and that a portion of the funds had been obtained as a "loan" from the Hospital Saturday Fund Committee of Birmingham, a charitable body The main points, however, which Dr BATEMAN tried to establish before the General Medical Council were that Dr IRVINE was aware of the character of the advertisements and that he had a direct pecuniary advantage in the success of the institution With regard to the first, Dr IRVINE at first stated that he had never seen one of the objectionable placards, but in cross-examination admitted that there was one in the institution, and in reference to the second point Mr WILLIAM COOK, the chairman of the Committee of the Hospital Saturday Fund of Birmingham, stated in his evidence that if Dr IRVINE was found to be worth more than £500 a year and the committee had the funds to pay he "supposed the committee would like to see him properly paid' On a careful consideration of the evidence the General Medical Council came to the inevitable conclusion that the charge against Dr IRVINE had been proved, but adjourned adjudication until the next session so that Dr IRVINE could consider his position This deliverance of the General Medical Council will commend itself to all members of the medical profession who have followed the case Dr IRVINE has undoubtedly sinned against the canons of medical etiquette Now that the opinion of the supreme court of medical ethics has pronounced against him he will doubtless sever his connexion with an institution which, although apparently formed with very good intentions, was run on lines which cannot be approved by the medical profession We entirely endorse the action taken by the General Medical Council and congratulate the council and officials of the Medical Defence Union on the fair, just, and open manner in which the case was conducted

◆

THE Christmas holidays are again upon us The lapse of nearly 2000 years makes no difference in their interest or their significance to the great bulk of our race The peace and goodwill promised in the dim past still recede into the indefinite future and the conflict of races shows little abatement But still we believe the promise to hold good, even while science, as it progresses with long strides, deals roughly with the dogmas which have their centre in the event which christens our holiday But still we keep our Christmastide, and, in spite of all that tends to spoil the simplicity of our belief, faith still survives and with it hope and charity We suspend our business in wholesale fashion and we try, or profess to try, to suspend our uncharitableness And if we are as a nation at war, as we shall be on next Christmas Day, the season will be a fitting one wherein to consider as a nation how to make the war, and make it quickly, a means of peace

Let nobody say, therefore, that we have no longer a use for Christmas Day A festival of charity, a date of general reconciliation, is more needed than ever, and we cannot begin the new century better than by carrying into it the Christmas spirit It is hard for many of us while our sons and brothers are still at the front fighting for the maintenance of our rights and influence for good in the world to enter with spirit into the gaiety which we associate with the season But the more we do so, the more complete will be the victory over the petty spite and misunderstanding of which for the moment we as a nation are the victims and the better will be our national health He is a poor physician who does not at times recognise the moral side of human nature and the enormous influence which it exerts on human life both in its national and its individual form Ours is a profession which has to aim at securing for every member of the community the healthy mind in the healthy body The advance in civilisation only emphasises the necessity for recognising our double charge What intelligent British practitioner does not know that for 12 or 15 months he has been dealing with human nature under conditions of depression and care which have complicated disease and antagonised the operation of his remedies The nation has been rich it has been able to eat and to drink to the full, but it has been restless, dissatisfied, and neurotic The state of war is not normal to us as a nation, though we generally contrive by the blessing of Providence to come out of war, possibly after many blunders, on the winning side Our great victories are those of peace, and peace is our greatest interest We do well, then, to make much of Christmas to refuse to believe that any brave men are our lasting enemies, and to cultivate the spirit of peace and goodwill A little good statesmanship in our politicians and our soldiers may make the world in the coming century a very happy world for the subjects of the QUEEN

Taking a more domestic view of Christmas holidays we find much to interest us as a profession To no one more than to a medical man can the disposition to abolish for a season the cares of the poor appeal, for no one knows better than the medical man what the stress of poverty really means to our less fortunate brethren A time when all are trying to do something to assuage the inequalities of circumstance is a time when in a sense the whole people become physicians

"All have to spare none are too poor
When want with winter comes
The loaf is never all your own
Then scatter out the crumbs
Soon winter falls upon your life,
The day of reckoning comes
Against your sins, by high decree
Are weighed these scattered crumbs

But we need to be on our guard against the evils of indiscriminate charity, and very specially against all encouragement of drunkenness The words of Lord ROBERTS pleading for care lest we tempt our returning soldiers into vice are still ringing in the nation's ears It is not too much to ask that whatever forms Christmas kindness to the poor may take it will not take the form of "treating" Coals, clothing, food, entertainment and all forms of personal kindness must supersede this discredited custom And the longer that charitable efforts are continued the better, it is a poor way of honouring Christmas to expend all our care for the poor in one day We are on the eve of new efforts to abate the extreme poverty which discredits our civilisation, and the more personal consideration each one of us can give to the problem the better

◆

WE have received two small pamphlets, published by Messrs John Bale, Sons, and Danielsson, Limited, Great

Titchfield-street, London, W. Their titles are, "Counsel for Young and Unmarried Men respecting Chastity," and "The Proper Discipline to be observed by Married People in regard to Conjugal Intercourse," and they are stated to be issued "on high medical authority and with episcopal sanction." Their object is sufficiently indicated by their titles. The medical authority concerned in the production dwells with suitable brevity upon the physiological aspects of the case and his observations are accurate and to the point. If we cannot speak as highly of the advice emanating from the "clerical" authority this is not because we do not see that a sincere attempt has been made to do good. But clerical admonitions would prove more impressive if they avoided the appearance of being founded upon an intimate acquaintance with what is right. Thinking men and women are not prone to adopt views the reasons for which they cannot follow, however sincerely those views may be urged upon them by teachers having a personal belief in their correctness. We have two or three general observations to submit upon the subject, and more than general observations we cannot make, for individual appetites so vary that we do not wish to be the medium for recording any hard and-fast limits, even while we see the benefit that might accrue to some people from such guidance. In the unmarried, and especially in the young, continence is the noble aim. We do not dwell for the moment (though this aspect is vitally important) upon the narrower and more selfish view of the physical and moral evils which incontinence may produce: we rather assume the higher ground that a man who ruins, or helps to maintain the ruin of, a female is a sinner against the social law of love. Each young man should act as a trustee for the chastity of every woman and should account as a personal insult and degradation any suggestion to mar her highest development into the type of womanhood. This is the ideal attitude towards unchastity, whether it be assumed out of physiological knowledge, out of faith in the beneficent effect of a Divine will, or (best of all) out of a fortunate blend of both reasons. But incontinence besets the married as well as those to whom sexual gratification is morally forbidden. In married life, as members of our profession know too well, there frequently occurs a reversion to primitive customs. The wife is still too often considered to be largely a mode of sensual gratification to the man instead of a helpmate, entitled to equal respect of her feelings and sense of dignity. This is well known to the medical man, for it is part of the routine of his life to receive confidences of a perfectly intimate character. And his counsel, based upon knowledge that no general laws can be laid down, is always towards moderation. But we would suggest to the Church a reform of the Marriage Service, which in its present terms encourages the belief that marriage is largely a device for the multiplication of children and that the wife in this respect is to "obey" the demands of a husband, however insatiable. Any teaching which appears to support this view can only debase, rather than elevate, married life. The Law, following in the steps of the Church, gives a carnal interpretation of marriage, and treats the tie as mainly one of sensual meaning, and so the full dignity of conjugal union is missed. We need an equitable and righteous reform, possible only under fresher and purer conceptions, and a more elevated view accordingly of the married state—a state in which the intellectual, moral, social, and spiritual affinities between man and wife shall be cultivated and sought, in place of the more debasing notion which is too generally sanctioned by Church and Law, and which largely forms the predominating element in popular views. The Law by the growing recognition of the personal rights of the wife has shown that its purview of married life is becoming larger and more liberal. Medicine plays its part by inculcating moderation. There are ways in which the Church might help.

Annotations.

"Ne quid nimis"

LORD SALISBURY ON THE HOUSING OF THE POOR.

The weighty words which Lord Salisbury has just pronounced on the housing of the poor will, we trust, be taken to heart throughout the land, but more especially by the new borough councils of the metropolis. We are glad to see that the anxieties caused by the war did not prevent the Premier from devoting some consideration to this most important social question. It is true that these questions are not disconnected, though at first sight they seem to be widely apart. A moment's thought, however, suffices to make it clear that it is not from the prosperous artisan class, but rather from among the unskilled labourers, that a considerable proportion of the rank and file of the army must be recruited. In the labour market the recruiting sergeant can scarcely compete with those who work nine hours a day for 9*d*. an hour It is among men who, when in work, earn less than £1 a week that the inducement to enlist must be the strongest. But, on the other hand, if the members of this, the poorer, class are obliged on account of their poverty to huddle together in overcrowded, insanitary houses, their physical powers will be so reduced as to render them unfit for military service. The evil, however, has gone even beyond this point, for workers who are earning higher wages and are willing to pay considerable sums in rent often find it difficult to obtain decent houses, at least in London. Addressing the National Union of Conservative Associations on Dec. 18th, Lord Salisbury recommended his party to devote all their powers to get rid of what he described as a scandal to our civilisation, namely—"the suffering which many of the working-classes have to undergo in order to obtain even the most moderate, I might say the most pitiable, accommodation." He then insisted that this was the most urgent of all social questions and hinted that it was not to be settled by the hard and fast conditions of the market. On the contrary, Lord Salisbury reminded his audience that he had attempted to pass a Bill so that the site of Millbank Prison should be sold at its cost price and not at its market price on condition that it should be used only for the purpose of erecting habitations for the poor. It is not creditable to the House of Commons that it should have rejected this proposal though it had been adopted in the House of Lords. Perhaps now that the grievance is becoming more and more menacing there will be a better disposition shown, and some readiness will be displayed to forego the driving of hard bargains—the exacting of the uttermost penny when this can only be achieved by bringing about the degradation, physical and moral, of large sections of the population.

"FAITH-CURISTS" CONVICTED AND IMPRISONED.

The United States have given birth to many strange sects who have endowed themselves with wonderful and eccentric names. As a rule, these little Bethels vegetate in comparative seclusion, so that perhaps the "Fire-Baptized Holiness Mission" is not altogether sorry at having acquired the publicity of cheap martyrdom. Self-advertisement has become a fine art in America, but we should think that the line might be drawn at manslaughter. Among the peculiarities of this peculiar sect with a peculiar name are their faith in mind cure and their total disbelief in medicine and medical men. Certainly a good deal may be said as to the influence of the mind over the body, but even this theory presupposes the existence of a mind to influence the body. It is doubtful, however, if anyone would venture to define what amount of mind force or will power an infant seven months old can be directed to exercise over himself. Edward Black was the name of the infant in question. According to the statement of his mother, he had been sickly from birth and he was ill when he was confided to the charge of Henry E. Sollenberger and Ezra Sheets, who are "faith-curists" of the "Beulah Orphanage" belonging to the "Fire-Baptized Holiness Mission." The child was first fed on sterilised milk and then on condensed milk, but in a few days he died. Summoned to appear before the court at Philadelphia on the charge of manslaughter, Sollenberger pleaded that he was taught by the Bible to leave all persons who were ill in the hands of the Supreme Being and that medicine was poison to the human system. He did not explain why he had not left the milk in the hands of the Supreme Being instead of having it sterilised, which was surely a medical precaution and quite as unnatural or artificial a process as the taking of medicine. The defendant, it appears, was born in Kansas and was by trade a carpenter, but he declared that he was "controlled by the Spirit" which "called" him to Philadelphia and "directed" his actions. Neither the judge nor apparently anyone else in the court doubted the defendant's sincerity; but as he openly proclaimed that "doctoring was against his principles" and that therefore he had not attempted to obtain any medical advice, both Sollenberger and Ezra Sheets were condemned to three months' imprisonment. 'They cannot complain that this is a severe sentence;' we hope it may suffice to maintain the law and to prevent fatal experiments being made upon defenceless infants. We are not sure but that the mother should likewise have shared in the penalty, for it is a strange aberration on the part of parents to confide sick children to people who are known to repudiate all idea of seeking medical advice. If this sort of thing was sanctioned "the making of angels," as the French say, which constitutes the most profitable phase of baby-farming, would meet with serious competition from unscrupulous "faith-curists." Under the mantle of religious convictions much could be done to hasten the departure of unwelcome infants.

THE BOROUGH OF LAMBETH AND BACTERIOLOGICAL EXAMINATIONS.

Dr. Joseph Priestley, medical officer of health of the borough of Lambeth, has issued a very interesting report dealing with the results of 1000 bacteriological examinations made in the borough laboratory. The laboratory was opened in 1899 at Loughborough, and the work done has been mainly concerned with tuberculosis, typhoid fever, and diphtheria. Out of 200 samples of sputum from doubtful cases of tuberculosis 68, or 34 per cent., were found to contain tubercle bacilli. Of 178 samples of blood from suspected cases of typhoid fever 97, or 54 5 per cent., gave the Widal reaction. Of 620 samples of membrane and secretion from the throats of patients suspected of being affected with diphtheria 191, or 30 8 per cent., gave the true Klebs-Loffler bacillus. A good example of the value of bacteriological examination is the following history of a school in Lambeth:—

> "Out of a total of 137 scholars 57 suspicious throats were from time to time examined bacteriologically, with the result that 48 showed the presence of bacilli—four the Klebs-Löffler (true diphtheria) bacilli and 38 the Hoffmann (pseudo-diphtheria) bacilli. The four cases of diphtheria were at once sent to the hospital, while the 38 pseudo-patients were isolated in a special isolation house belonging to the school, but distinct and away from the main building, and not allowed to return to the main building until further bacteriological examination of their throats failed to show the pseudo-bacilli. The preventive measures which I suggested, and which were strictly carried out by the medical attendant, may be mentioned. The scholars were carefully watched from day to day, suspicious throats swabbed and examined bacteriologically, and afterwards isolated, or not, according as such examinations gave positive or negative results. In this way the whole of the doubtful cases were separated out and kept under observation in an isolated building, where they remained until such time as further bacteriological examinations showed the scholars' throats to be free from infection. Then, and not till then, were the scholars gradually drafted back into the school, after their clothes and persons had been efficiently disinfected. The result justified the means taken, as the outbreak of pseudo-diphtheria has been stamped out; whilst, although pseudo-throats appear, in the light of our present knowledge, to form a suitable breeding ground upon which true diphtheria may at any time become ingrafted and spread rapidly (the pseudo-bacilli apparently at times changing into the true diphtheria bacilli, and *vice versâ*) only one such true diphtheria case developed, making a total of five diphtheria cases altogether. It was not necessary to take the extreme measure of closing the school and distributing the scholars over various parts of London and elsewhere—a procedure that may have to be adopted at times—e g., when the school buildings are found to be insanitary, the school attendance much interfered with, &c."

These results show very well how great an aid to preventive medicine is a careful bacteriological examination.

ALCOHOLIC HOMICIDE.

Dr. W. C. Sullivan, deputy medical officer of Her Majesty's Prison, Pentonville, has published in the October number of the *Journal of Mental Science* a paper on Alcoholic Homicide based on a series of 80 observations, comprising 36 cases of homicide and 44 cases of grave homicidal attempts "in which the criminal act could in some considerable measure be assigned to the influence of alcoholism." To illustrate the special characteristics of the homicide of alcoholism several cases are described, of which the following (the first) is typical It was that of a male, aged 28 years, a sailor. The father was mentally unstable and was "subject to fits." The paternal uncle died insane and the patient himself was said to have had sunstroke. When sober he was of normal feeling and intelligence, but when intoxicated he was violent. He had three times been convicted for having been drunk and disorderly. On the evening of the eleventh day of a severe drinking bout he was seen going home with his wife and appeared to be on "boisterously affectionate" terms with her. During the night he cut her throat with a razor as she lay in bed and then made an almost successful attempt to commit suicide with the same weapon. He professed to have no memory of the act and could not at any subsequent time suggest a motive for it. While under treatment for his self inflicted wound he suffered from the severe digestive and nervous symptoms of alcoholism. Dr. Sullivan regards this as a good example of the "automatic type of alcoholic homicide. As in the corresponding form of alcoholic suicide[1] there is an entire absence of apparent motive, the act is committed in a state of acute intoxication, no trace is left in the agent's memory, and finally, to show the identity in nature and origin of the two impulses, the murder is followed by a suicidal attempt." In explanation of this it is pointed out that the cerebral condition in alcoholism is one which may be termed excitability of the so-called psycho-motor or kinæsthetic functions. In this condition the slightest suggestion arising from whatever cause within the mind tends to be translated into action with extraordinary facility. A clear instance of such agency, trivial in itself but potent in alcoholics, is afforded in a case recorded by Professor Despine, where one of four drunkards who were carousing together suggested the hanging of the most intoxicated of the party—a suggestion which was promptly carried out, with results which only failed of being fatal through the accident of outside intervention. In other alcoholic subjects murder of a wife may be the result of delusions of marital infidelity or of poisoning, which are very prone to develop in chronic alcoholism. In others again a state of sub-conscious automatism similar to that of the post-epileptic stage may be associated with the homicidal act. In few cases is there any degree of lucidity and purposiveness in the act. Chronicity and long indulgence in the drinking habit are the natural antecedents of true alcoholic homicide, except in cases where there exists initially some degree of mental instability, hereditary or acquired. There may then be a very precocious development of impulsive automatism in which the rôle of intoxication is largely overshadowed by that of the primary mental disorder. Cases of this kind form the transition to insane homicide unconnected with alcoholism

THE SANITARY STATE OF MADEIRA.

Dr. Krohn of Funchal, who, in collaboration with an Englishman, Dr. F. J. Hicks, has charge of the Seaman's Hospital, is the author of a report on the sanitary condition of Madeira which has been published in the *Archiv fur Schiffs- und Tropen-Hygiene*, vol. iii., 1899. The water-supply of Funchal is of two kinds, one for drinking purposes and the other for gardens, baths, and closets. The former, which is distributed by means of "hermetically closed conduits," is obtained from five chief sources above the town, and according to analyses made in England its quality is excellent in every respect. There are no sewers in the island, night-soil being diverted into loose-bottomed cesspits, but happily under such circumstances water-closets are the exception. Scavenging in Funchal is only fairly attended to, but the markets are maintained in an exemplary state of cleanliness. Madeira is celebrated for the magnificence of its climate, and yet according to Dr. Krohn the mortality amongst the natives was at the rate of 27·4 per 1000 in 1897, and higher still during the two preceding years. Out of 1067 deaths from all causes (diseases) in 1897 there were 84 from phthisis pulmonalis. Tuberculosis, says Dr. Krohn, is widely spread among the lower classes, as are also pneumonia and bronchitis, which are very fatal to children. Scarlet fever and small-pox are of rare occurrence, but diphtheria, measles, and whooping-cough are common, while typhoid fever is extremely prevalent among the lower orders. The type of these affections is, however, remarkably mild, the mean mortality of the last-mentioned during 12 years having been 0·97 per 1000 inhabitants. The disease which is most prevalent in Madeira would seem to be diarrhœa, but cases of dysentery are only occasionally met with. Leprosy, which formerly was very common in the island, is now said to be dying out, the number of patients under treatment in the special hospital being only four, of whom two were suffering from elephantiasis. There are five hospitals in Funchal and its vicinity: (1) the military hospital, which "leaves much to be desired from every point of view"; (2) the civil hospital, containing 80 beds; (3) the above-mentioned lazar-house; (4) the Donna Amelia Hospital, which is reserved for patients suffering from pulmonary tuberculosis; and (5) the Seaman's Hospital, founded by Dr. Goldschmidt, where mariners of all nationalities are admitted on payment of two and a half francs per diem. Notwithstanding the drawbacks which he enumerates Dr. Krohn strenuously asserts that Funchal makes a most admirable sanatorium for sufferers from tuberculosis and malaria. No doubt the natural advantages, including complete freedom from malaria, are very great, but evidently much might still be done to supplement them. Madeira was originally discovered in a romantic way by an Englishman, Mr. Macham, in 1345, and it was not until 1419 that it was occupied by the Portuguese. In 1807, when the Royal Family of Portugal emigrated to the Brazils, Madeira was taken possession of by Admiral Hood and Lord Beresford, but after some time it was restored to the Portuguese Crown.

THE RÔLE OF CONSANGUINITY IN THE ETIOLOGY OF EPILEPSY, HYSTERIA, IDIOCY, AND IMBECILITY.

A contribution of interest on the above subject appears in a recent *Thèse de Paris* (1900) by Dr. Theophile Gillet of Paris, dealing with the results of consanguineous marriages in relation to certain neuroses and psychoses. Dr. Rilliet and Dr. Barthez in their classical "Treatise on the Diseases of Children" (1859) had stated that the results of consanguinity of parents were as follows. First, fewer births; secondly, more miscarriages and still-births than the average; thirdly, weakness (physical and moral) of the surviving children; fourthly, a special tendency in the offspring to diseases of the nervous system, such as epilepsy, idiocy and imbecility, deaf-mutism, and local cerebral palsies; and lastly, a special proclivity in the offspring to tuberculous degeneracy. It has since been stated that among the more frequent results of consanguinity in the parents are such abnormalities as albinism, deaf-mutism, and retinitis pigmentosa in the offspring, even in cases where but one parent showed the specific morbid taint. The observations of Dr. Gillet were made at the Bicêtre during 11 years (from 1889 to 1900), during which period 1228 children were under care and treatment. Inquiries were also made into the histories of 425 girl patients at the Fondation Vallée, Paris, an institution for children suffering from nervous diseases. The total number of cases investigated was, therefore, 1653. Inquiries into the family histories of these patients elicited the fact that there were 45 instances of consanguineous marriage in the parents. These 45 families were minutely studied, with the result that the offspring of these families taken *en bloc* showed 19 cases of idiocy, 14 of epilepsy (idiopathic or symptomatic), eight of imbecility, three of hydrocephalus, one of chorea, and one of idiocy, a total of 46 grave neuroses and cerebral defects. The relative degrees of consanguinity were as follows. In 28 instances the father and mother were first cousins, in nine they were the children of first cousins, in seven instances they were cousins of the third, fourth, and fifth degree, and in one case uncle and niece. Inquiry into the condition of their children during infancy revealed the fact that convulsions and meningitis were notably prevalent, while idiocy or imbecility and chorea were also found to prevail in an abnormally high degree. Taking the total of all the surviving children of these consanguineous marriages it appeared that 2 7 per cent of them suffered from idiocy, epilepsy, imbecility, hysteria, or other grave cerebral disorders—a proportion very much larger than that generally present among the offspring of those in the same rank of life but who had not contracted consanguineous marriages

THE ROYAL INSTITUTION OF GREAT BRITAIN

AMONG the Friday evening lectures to be delivered before Laster, 1901, at the Royal Institution are "Gases at the Beginning and End of the Century," by Professor Dewar, on Jan 18th; "The Existence of Bodies Smaller than Atoms" by Professor J J Thomson on Feb 15th, and "Some Recent Work on Diffusion," by Mr Horace T Brown, on March 22nd The Tuesday arrangements will include a series of five lectures on "The Cell as the Unit of Life,' by Dr Allan Macfadyen, and they will be delivered on Feb 26th, and March 5th, 12th, 19th, and 26th "On the Origin of Vertebrate Animals' will be the subject of three Thursday lectures by Dr Arthur Whilley, the dates of delivery being Jan 17th, 24th, and 31st

THE WATER-SUPPLY OF NEW YORK CITY

THE water supply of New York, though more plenteous by far than that of London and than that of most of the large European cities, is the cause of much anxiety to citizens and sanitarians It is argued, and undoubtedly with truth, that the supply for Greater New York is not keeping pace with the growth in population, and that under present conditions this supply will soon become inadequate The Merchants' Association of New York have recently made an exhaustive study of the question and as a result of their investigations the following data have been gathered All the supply of Manhattan and the Bronx—the two boroughs constituting New York until 1897—is furnished by the city with the exception of 1,000,000 gallons daily supplied by a private company Brooklyn is almost wholly supplied with water from ponds and "driven wells,' all but 7 per cent of which are under municipal control Richmond and Queens, the two other boroughs which make up Greater New York, are supplied by wells owned nearly entirely by private corporations The average daily consumption of all these boroughs in 1899 was 371,778 000 gallons, an estimated average daily consumption per capita of 103 gallons The total daily yield was about 409,000 000, but in the boroughs of Brooklyn, Queens, and Richmond the present consumption is shown to be nearly equal to the present supply, while it is estimated that in 1903 the consumption in Manhattan and the Bronx will nearly equal the supply at that time available under present methods The conclusions reached, therefore, are that an additional supply of water for the entire city is imperative, and, seeing that from six to seven years will be necessary to complete the work of furnishing this additional supply, that immediate steps should be taken to make a beginning The plan most generally favoured would appear to be the utilisation of the Hudson river above Poughkeepsie about 70 miles from New York The Medical Society of the County of New York has been interesting itself in the matter and Dr Chapin, the chairman of the Committee on Hygiene of that body, has lately published in his annual report on the public health of New York a lengthy review of the situation as regards the water supply Referring to the Hudson River scheme, of which he approves, he says "It is proposed to filter this water, the experience of other cities having shown that filtration is a perfect method of purifying water, being, indeed only a scientific reproduction of a process of nature That filtration is effective in removing impurities and germs of disease is amply proved by the experience of Albany, Poughkeepsie, London, Hamburgh, and other cities The reduction of typhoid fever and diarrhœal diseases with the introduction of filtered water has occurred in a large number of cities in Europe and America ' Dr Chapin also strongly advises that any arrangement for increasing the water supply of New York be under municipal management and control and not by contract with any private company, the cost to the consumer being almost always less under public control than under private ownership According to our New York correspondent much dissatisfaction with the quality of water supplied to New York City is now being evinced by the general public so that it seems probable that immediate steps will be taken to remedy the evil

THE DIAGNOSIS OF POTT'S DISEASE

BEFORE the Section of Orthopædic Surgery at the New York Academy of Medicine Dr H Gibney recently read a paper on the Diagnosis of Pott's Disease, which was illustrated by the exhibition of photographs and the presentation of some interesting patients Dr Gibney said that photographs clearly presented the attitudes but failed to display the characteristic movements and deportment of the patient affected with Pott's disease, but the accompanying figure from his collection graphically demonstrates the over erect attitude which was assumed by one of the sufferers throwing light on the mechanism of the production of the lordosis which appears as a compensating curve below the kyphos

DIPHTHERIA BACILLI IN HEALTHY NOSES AND THROATS

THE *Boston Medical and Surgical Journal* of Nov 22nd contains a valuable paper on this important subject by Dr Francis P Denny, bacteriologist of the Brookline Board of Health Kober found from a review of all the reports which he could collect that of healthy persons who had not been exposed to diphtheria 7 per cent had Klebs Loffler bacilli in their throats, while of those who had been thus exposed 18 8 per cent exhibited these organisms But his own investigations showed only 0 83 per cent among the non exposed and 8 per cent among the exposed The high percentages found in literature are to be explained by the fact that many of the cultures were made from individuals living in institutions or in the crowded tenements of large cities Another reason for the high percentages is that in many reports no distinction is made between virulent and non-virulent bacilli. The latter do not differ morphologically from the Klebs-Löffler bacilli but they are probably not a source of danger. They may show slight variations of growth from that of virulent bacilli on certain media, the most important of which is failure to produce acid in sugar bouillon. These bacilli have never been made virulent by experimental cultivation. The bacilli found in healthy persons who have been exposed to the disease are usually virulent. Virulent bacilli may multiply in the throats and noses of certain persons without producing symptoms because these persons are immune to the disease, just as they multiply in the throats of those convalescing from diphtheria. These healthy individuals with virulent bacilli in their throats can communicate diphtheria to others. In coughing, sneezing, and even, according to Pflügger, in speaking, the bacilli are scattered about. They are carried from the mouth on towels, handkerchiefs, forks, spoons, and cups. Many outbreaks of diphtheria in children's institutions which persisted for a long time, despite the fact that all sick children were promptly isolated and the rooms were disinfected, have been quickly stamped out when the healthy children's throats have been tested and when those children whose throats contained bacilli have been isolated. In examining a healthy person for the bacilli of diphtheria cultures should be made from both the nose and the throat, for bacilli may be present in the former and absent in the latter. It is very important to remember that antitoxin prevents only the development of symptoms and not the growth of bacilli in the throat. Thus its prophylactic use may favour the spread of diphtheria, for the artificially immunised persons who otherwise would have developed symptoms and have been isolated are allowed freedom while there are abundant bacilli in their throats. Hence the importance of making cultures from their throats and isolating them if necessary. The nurses in charge of cases of diphtheria frequently have bacilli in their throats without developing the disease. The following narrative shows the value of the examination of the throats of healthy persons for the bacilli of diphtheria. Two children of a milkman's family were sent to hospital suffering from diphtheria. As it was thought that other inmates of the house might harbour the bacilli in their throats and infect the milk cultures were made from their throats. These were negative. About three weeks later diphtheria began to appear among the milkman's customers. Cultures were again made from the milkman's household. Three healthy men, two of whom did the milking, were found to harbour the bacilli of diphtheria, which were very abundant and which proved to be virulent to guinea-pigs. At Brookline during a recent epidemic of diphtheria culture outfits were kept at all the schools. When a child was taken ill with diphtheria inspectors made cultures from those children who sat nearest to the affected child in school. When more than one case occurred in a room cultures were made from all the children in that room. In one case three children who sat in adjoining seats were taken ill simultaneously with diphtheria, and cultures of the bacilli of diphtheria were obtained from the throats of two perfectly healthy children sitting near them.

THE HEREFORDSHIRE GENERAL INFIRMARY.

MOST visitors to the city of Hereford will remember the General Infirmary buildings situated in the picturesque grounds overlooking the river Wye. Established as long ago as 1776 the infirmary with its 100 beds has been carrying on most serviceable work, not only among the inhabitants of Herefordshire, but there has been found room in its wards for patients from the adjoining counties of Worcester, Monmouth, and Radnor. In order to secure more sustained support in the county it was decided early in the present year to make certain alterations in the form of management and at a recent meeting of the governors some definite changes were made. The first proposal was for a change of name. For a century and a quarter the institution has been known as the Hereford General Infirmary and it was suggested that a more comprehensive, though certainly less euphonious, title would be the Hereford County and City Hospital. After several other names had been discussed it was decided, wisely we think, to make the simple alteration to the Herefordshire General Infirmary. With only one other material modification of the constitution are we now concerned and that is in connexion with the representation of the medical staff upon the board of management. Hitherto the whole of the staff have occupied seats upon the board, but it would appear from the reports in the local newspapers that some of the lay members have occasionally found themselves in a minority with the whole of the staff opposed to them; it was decided, therefore, that the staff should elect two of their number upon the board of management. The medical staff are stated to have quite acquiesced in this proposal, so that if they are satisfied we can have little to say on the matter, but as the two medical members will be only one-sixth of the whole board no harm would have been done if the number had been doubled, for even then they would have been in a minority.

WORKMEN'S DWELLINGS IN COLLIERY DISTRICTS

THE exceptionally flourishing condition of the coal trade has given special prominence to the question of the housing of the working-classes in colliery districts, for the higher wages obtained by colliers has attracted to the coal-pits quite an army of labourers who have never before worked underground. In the South Wales coalfield especially the want of houses is being noticeably felt and houses are allowed by sanitary officials to be occupied which ordinarily would be condemned, solely because there is absolutely nowhere else for the occupants to go, while it is almost the exception in many localities to find a cottage house part of which is not sublet in "apartments" or to single men lodgers. Usually private enterprise is to be relied upon to provide a remedy for such deplorable conditions as those indicated, but the present high price of building materials and the increased wages that are now prevailing are quite sufficient to make the speculative builder hesitate before embarking upon any very extensive undertaking. It is gratifying to find that in some districts the sanitary authorities are themselves undertaking the duty of providing suitable housing accommodation. At Nantyglo Part III. of the Housing of the Working Classes Act, 1890, has been adopted and the district council are now in a position to erect lodging-houses and workmen's cottages. At Merthyr Tydvil the working men have for several months been urging upon the urban district council the desirability of erecting workmen's dwellings and an initial step has been taken in seeking for power to borrow the sum of £15,000 for the purpose of building in the first instance 100 cottages. At the Local Government Board inquiry recently held in connexion with this scheme it was stated that each house would have three bedrooms and would let at 5*s.* weekly. The ground-rent of each house is £1 per annum and the land is taken upon lease for 999 years. Merthyr Tydvil has long had an unenviable reputation even among the insanitary towns of Glamorganshire. It is a great pity, therefore, that some of the leading and most influential inhabitants of the town should be found actively opposing the efforts of the council in dealing with a most difficult problem. The sole argument of the opposition appears to be the very selfish one that if the cottages do not pay their way those who live in the more highly rated portion of the district will be called upon to pay their proportion of the loss.

THE CALEDONIAN MEDICAL SOCIETY.

As will be seen by a notice in our advertisement columns, the Caledonian Medical Society is offering two prizes of the value of £20 and £10 respectively for the best original essays upon subjects selected from the "Domain of Celtic Ethnology, History, Philology, or Medicine." The subjects are very wide and so is the area of competition, for it is open to everyone and should attract a large number of candidates Celtic ethnology, including, we suppose, folk-lore, is an entrancing subject and one which should be the cause of most interesting essays. The essays must be sent to the secretary, Dr. S R Macphail of Rowditch, Derby, by Jan. 1st, 1902

THE ALEXANDER MEMORIAL PRIZE.

OWING, probably, to the pressure of work entailed on the officers of the Royal Army Medical Corps by the war in South Africa, no essays competing for the prize of £50 and a gold medal have been received within the limits of time required. The committee have therefore resolved to offer the same subject for the next competition—viz., "Injuries to joints and long bones caused by modern small-arm projectiles their nature, diagnosis, and treatment, with special reference to the appliances required and available on field service." Essays must reach the president of the committee on or before Dec. 31st, 1902, must bear a brief motto, and be accompanied by a sealed envelope similarly superscribed, containing the name and address of the author. No essay should exceed about 20,000 words, exclusive of tables which may be added in the form of appendices. The competition is limited to executive officers of the Royal Army Medical Corps on full pay, and professors and assistant professors at Netley are not eligible while so employed.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN: AN APPEAL.

CHRISTMAS is heralded by the usual procession of appeals to charity. It is not too much to say that the majority of these are deserving of sympathetic recognition. Not a few are worthy in the highest degree. It is no less true that only the longest purse can even attempt to alleviate their innumerable necessities. It thus becomes for most of us a plain duty to select with the best judgment that we can those benevolent objects the furtherance of which appears to be most desirable. A list of such objects can have no constant composition. Its character will vary with the views of each compiler and we would be the last to prejudice this liberty of individual judgment. It is assuredly with no such motive that we take this opportunity of directing public attention to the needs of one such deserving effort of charity. It is the National Society for the Prevention of Cruelty to Children. The society, notwithstanding that it has many and influential supporters, has not passed through the financial crisis involved by the war in South Africa without suffering some curtailment of its revenue. In view of the fact that its weekly expenditure amounts to the sum of £1100, a moderate income in itself, this is a serious consideration. Moreover, its work is entirely concerned with emergencies, which, however they may be regretted, cannot be overlooked without serious injury to the many illtreated children whom it seeks to help. Thus the extension of its operations is a matter of practical necessity. We have repeatedly explained the nature of these operations. The judgment with which they have been carried out is conspicuous. The society has earned its meed of approval at the hands of the bench, of the police authorities, and even of parents out of whose cruel misdemeanours it has evolved the order and happiness of normal home life. It is hardly needful to remind our readers that whatever is saved and strengthened in the childhood of to day will go to fortify the manhood and womanhood of the coming generation Nor need we rehearse the part which has been taken by the society in promoting every recent legislative measure for the welfare of the young. But we trust that its endeavours will be aided by the liberality of the country in whose interest its work is done. In particular we would express a hope that a serious effort will be made to wipe off a deficit of £8000 which has acted as a drag upon the movement of the society during the present year.

THE INCREASED PREVALENCE OF APPENDICITIS IN SWITZERLAND.

OUR Zürich correspondent writes:—Dr. Haemig, first assistant of Professor Kronlein, made an interesting communication on Dec 6th, at a meeting of the Zürich Medical Society, on a series of cases of appendicitis observed at the Surgical Clinique of Zurich from 1881 to 1900, the 20 years during which Professor Kronlein had been in charge of the clinique The numbers of cases admitted increased from year to year, so that against 45 cases in the first 15 years there were respectively 13, 21, 35, 41, and 48 cases of admission in the last five years. Of these 203 cases, in 35 there was no operation, five of the patients being in a hopeless condition, and in the other cases operation being considered to be unnecessary. 51 patients had to be operated upon in the acute stage for abscess, four of these cases terminating fatally; in 27 cases generalised peritonitis had already supervened and of these 21 terminated in death, notwithstanding immediate operation. 91 patients were operated upon in the "free interval" and all recovered. The mortality percentage of the cases was 14, but if only the cases operated upon in the acute stage, without any generalised peritonitis, and those operated upon in the "free interval" be considered it will be seen that 142 cases had a mortality of only 3½ per cent Dr. Haemig laid due stress on the desirability of operating in the "free interval" and if possible after the first severe attack of appendicitis. The fact of the greater prevalence of appendicitis among men (70 to 30) is accounted for, he considers, by the better blood-supply of the appendix in females.

THE WAR AGAINST TUBERCULOSIS IN CANADA

THE Ontario Legislature has recently adopted a special Act to authorise the establishment of sanatoria for the treatment of phthisical patients. The usefulness of such institutions is generally acknowledged and they already exist in Switzerland, Germany, Belgium, and other countries. They differ, we take it, from a hospital such as the Brompton Hospital for Consumption, because they are not meant for acute cases and are not erected in the towns to which they belong, but in some more or less distant locality where the topographical and climatic conditions are specially favourable for the treatment of the disease. At the onset, however, the difficulty arises as to who shall be responsible for the expense of maintaining and building a sanatorium of this description. The medical officer of health of Toronto is endeavouring to solve this problem by proposing what can only be described as a mixed system. He does not suggest that a municipal sanatorium should be created, but he nevertheless calls upon the municipality to give a grant of $50,000 in aid of such an institution. In exchange for this grant he proposes that philanthropic institutions and charitable persons should supply an equal regards modern surgery, and to interpret their wishes to the lay committee. His interest in his work was very great. Hardly a day passed while he was in Oxford that he did not spend hours in becoming acquainted with all the current details of administration. Last spring he had to be absent for some months for the sake of his health. He went to Italy and seemed to a great extent to have recovered. In July, however, a recrudescence of disease occurred and he was forced to resign the treasurership, as he felt that the climate of this country was impossible for him. It was largely through his appreciation of the requirements of modern surgery that the new operating theatre, of which we gave an account in THE LANCET of June 23rd, 1900, p. 1822, was built. Sir John Conroy, who was born in 1845, was educated at Eton and Balliol, being a Fellow of the latter society and Bedford Lecturer and a Fellow of the Royal Society.

THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD AND THE METROPOLITAN WATER-SUPPLY.

ON Thursday, Dec. 13th, Mr. Long, the President of the Local Government Board, received a deputation from the London County Council on the subject of the water-supply of London. The new Minister thus early in his career was able to make a statement of the views which he holds on this important subject. The Government, he said, had nothing to conceal as to their policy and he was somewhat surprised to hear that the London County Council proposed to introduce during the next Parliamentary session a Bill to enable them to acquire the businesses of the present metropolitan water companies. The policy of the Government in regard to a similar Bill which the London County Council had introduced last year was unmistakeably shown, and the Bill was rejected. The time during which he had been at the Local Government Board had, Mr. Long pointed out, not been sufficient to enable him to study the whole of the question of the London water-supply, but he had become convinced that the solution of the problem was one which would require much consideration and this he promised it should have. If as a result of his study of the question he found that a course could be satisfactorily and definitely settled on, and if the other members of the Government should agree with the solution which he proposed, it was his intention to introduce a Bill dealing with the subject, not during the next session, but in the session immediately succeeding it. With a matter of such complexity and one involving such vast interests it was obviously impossible for him to deal thoroughly during the next session and he therefore regretted that the London County Council had decided to introduce again during that session a Bill similar to that which the Government had found it necessary to oppose last summer. The Government held that the future management of the London water-supply should be placed in the hands of a statutory authority representing the whole area and not a part only of the area of Water London. In regard to the manner in which the representation should be given to any new Water Authority which might be formed the President of the Local Government Board declined to give any pledge, and as to the whole question he said that he would be glad to have the views of the metropolitan boroughs and of those extra-metropolitan authorities which are within the area of supply of the London water companies. Mr. Long will find when he studies the evidence given before Lord Llandaff's Commission that the outside authorities have already spoken with no uncertain voice on the matter. It is satisfactory to note that the President of the Local Government Board confessed that the more he looked at it the more he was impressed with the difficulties of the question and with the risk which the ratepayers would run if they purchased the present undertakings. Mr. Long is already known as an able and strong Minister. The fact that he has thus early in his new office realised that he has a difficult problem to settle is a matter for congratulation. The fact that he has at once definitely promised that he intends immediately to grapple with the difficulty is most satisfactory.

ARSENIC IN ARTIFICIAL MANURES.

DURING the past week our Laboratory Commissioners have undertaken the examination of a number of substances, including certain foods and drugs in common daily use, in the preparation of which sulphuric acid is used. It will be found after a few moments' consideration that a fairly lengthy list of articles of every-day use may thus be drawn up. The results are not yet ripe for publication, but we feel bound to divulge one important result since the disturbing announcement has this week been made by the analyst of Manchester that arsenic has been found in malt in a quantity equal to that found in glucose or malt substitutes. Moreover, arsenic was found in beers which were known to be brewed from malt and hops only. Now that this remarkable statement has been made we may say that we have found, in the course of the inquiry alluded to, artificial manures to be rich in arsenic easily soluble in water. This is hardly surprising, since the basis of artificial manures—namely, superphosphate of lime—is made by acting on ordinary bone ash with common oil of vitriol. The important point is that it has been established that plants to which arsenical manure is applied take up arsenic in their tissues. Cabbages and turnips gathered from fields manured with superphosphate have given unmistakeable evidence of the presence of arsenic. It is probable that arsenic accumulates in the soil which is constantly being dressed with superphosphate, so that plants raised on such soil would absorb arsenic and exercise an injurious effect on the health of man and animals. The question arises, therefore, may not the arsenic in malt be traceable to the somewhat large amount of arsenic inevitably present in artificial manures? This aspect of the subject is very serious and needs further inquiry. We shall return to it in a future issue, when we hope also to be able to record the results obtained in an examination of other more or less familiar articles, in which arsenic may possibly be introduced through the employment of impure sulphuric acid in the course of manufacture.

THE WORCESTER GENERAL INFIRMARY AND ITS ANÆSTHETIST.

WE learn from the *Worcestershire Chronicle* of Nov. 24th that at a meeting of the committee of the Worcester General Infirmary it was decided to discontinue the existing arrangement whereby the infirmary obtained the services of a special officer to undertake the administration of the anæsthetics. By the new arrangement the anæsthetics are to be administered by a member of the surgical staff. We believe it to be extremely important that every hospital in which a large number of operations are performed during the year should have an anæsthetist attached to the staff, and the step which has been taken at Worcester appears to us a retrograde one. From the report before us we gather that the gentleman who has been acting as anæsthetist is not a member of the staff of the infirmary but that he conducted the anæsthetics for the staff and received a small honorarium for his labours. The committee, as it appears, have in a fit of frugality determined to forego the luxury of possessing a paid anæsthetist and to employ the money in other ways. What ways these are do not concern us. The broad question at issue is, Should a provincial hospital in which serious operations are constantly performed have to rely upon the services of any member of the staff who may be available for the conduct of the anæsthetics? We think not Busy practitioners cannot give their time to the work and no man is a satisfactory anæsthetist unless he is regularly employed in giving anæsthetics Where there is no anæsthetist in a hospital the most responsible work of giving the anæsthetics is likely to devolve upon a junior house surgeon who may be without anything but the most limited experience For, as we have recently pointed out, medical students too often receive no instruction in the giving of anæsthetics The constantly recurring fatalities under chloroform in provincial as well as in London hospitals when inexperienced men are giving the anæsthetic support our contention that the staff of every hospital where much operating is done should comprise an anæsthetist The poor and helpless who come to the hospitals have a right to have their lives made as safe from inexpertness or ignorance in an anæsthetist as in a surgeon or a physician

THE CHAIR OF ANATOMY AT THE ROYAL ACADEMY.

THE vacancy in the chair of Anatomy at the Royal Academy of Arts which was caused by the death of Mr William Anderson has been filled by the selection of Mr Arthur Thomson, Professor of Human Anatomy in the University of Oxford Professor Thomson is already known in a similar connexion owing to his holding the lectureship on anatomy in relation to art at the South Kensington Art Schools He is also the author of a most admirable handbook of anatomy for art students We are sure that all who know Professor Thomson will rejoice at the selection which has been made, and nowhere will more pleasure be felt than at Oxford, more especially in the medical school

THE death is announced of Mr Lionel E Kay Shuttleworth at San Remo Mr Kay-Shuttleworth, who was a Member of the Royal College of Surgeons of England, practised at San Remo, and also held the post of H B M Vice Consul there

THE council of King's College, London, have elected Dr Arthur Robinson, at present Lecturer on Anatomy in the Middlesex Hospital Medical School, to the Professorship of Anatomy in succession to the late Professor A W Hughes

MR WILLIAM VERNON, M R C S Eng, has been appointed Knight of Grace of the Order of the Hospital of St John of Jerusalem in England

THE Council of the Borough of Lambeth have unanimously increased the salary of their medical officer of health (Dr J Priestley) by £100 per annum

PRINCE OF WALES'S HOSPITAL FUND FOR LONDON

A MEETING of the general council of the Prince of Wales's Hospital Fund for London was held at Marlborough House on Dec 18th, the PRINCE of WALES being in the chair, to receive the report of the distribution committee

Lord ROTHSCHILD presented a statement of the financial position of the Fund up to Dec 14th, which showed that up to that date the Fund had this year received £26 888 in annual subscriptions, £8523 from donations, undefined contributions, and newspaper collections £6038 from investments £1000 from a legacy by Madame Rosa Ann Deleglise, £1000 as an annual grant from the trustees of the London Parochial Charities for the maintenance of convalescent hospitals, and other smaller sums, making a total of £43 468 13*s* 1*d* He had been informed that the Fund would also receive £6000 from the League of Mercy this year, and he congratulated His Royal Highness upon such a substantial contribution, which showed His Royal Highness's wisdom and foresight in forming the league Notwithstanding the absence of any appeal for 18 months until a few days ago the annual subscriptions were so far £1200 more this year than last It was natural to expect some falling off in donations, which up to the present this year were £5000 less, after including those amounts mentioned in the executive committee's report In addition there was a legacy of £3000 from Sir H P Turner Barron, which the Fund might expect to be paid in 1901

The PRINCE of WALES moved, and the LORD MAYOR seconded the adoption of the treasurer's report, which was agreed to

Mr H C SMITH presented the report of the executive committee, which recommended that the sum of £50 000 should be distributed this year of which £49 000 should be awarded to hospitals and £1000 to convalescent homes This is an increase of £8000 on the amount distributed last year and last year there was an increase of £9000 over the previous year The report also stated that the visiting committee was this year increased to 27 members It consists of the following gentlemen —Lord Lister Sir William MacCormac, Bart, Sir Thomas Smith Bart, Dr W S Church, Mr John Croft Dr A B Duffin, Mr Christopher Heath, Mr N C Macnamara Dr Pavy, Dr E C Perry, Mr T Pickering Pick, Mr H Power, Mr Alfred Willett, Viscount Duncannon, C B Lord Sandhurst G C I E, Sir Trevor Lawrence Bart, Sir Henry Burdett, K C B, Mr Thomas Burt M P, Mr Charles Burt, Mr J G Craggs Mr Frederick M Fry, Mr W D Hoare, Mr H J King, Mr James C Marshall, Mr J Pierpoint Morgan, jun Mr Albert G Sandeman and Mr Hugh C Smith

Lord LISTER presented the report of the distribution committee for the year 1900 and Mr J G CRAGGS read the report of the convalescent homes committee

The PRINCE of WALES moved the adoption of these reports and Sir WILLIAM MACCORMAC seconded the motion The reports were unanimously adopted

A vote of thanks to the Prince of Wales for presiding was moved by the LORD MAYOR

HIS ROYAL HIGHNESS in replying, said I am sure we all realise what a great thing it is for the Fund that the City of London should give us its hearty support It gives me great pleasure to take this opportunity of thanking all those gentlemen who have assisted me in the great work of this institution—the members of the general council, the visitors to the hospitals, the executive committee, and the honorary officers I am very glad Lord Duncannon has been able to take Sir Savile Crossley's place and I cannot say how much we are indebted to Mr Craggs for the labours he gives gratuitously to the Fund We have all plenty to do so I will not keep you any longer, but I think we may separate to-day with the feeling that the Fund is in a very prosperous state and that the interests of our great hospitals are still kept well before the public I can only hope that as time goes on the Fund may increase in prosperity so that the great object we had in view, that of placing the hospitals of this great metropolis on a thoroughly sound financial basis, may be accomplished

The meeting then terminated

THE SANITARY INSTITUTE A DISCUSSION ON PLAGUE

DR F TIDSWELL, principal assistant medical officer of the Government of New South Wales, opened an interesting discussion on plague at the Sanitary Institute on Dec 12th by reading a paper entitled "Some Practical Aspects of the Plague at Sydney" A feature in the delivery of this paper which enabled the audience which was not entirely composed of medical men, more clearly to understand Dr Tidswell's views was the ample illustration of points in diagnosis and etiology by means of lantern slides Dr Tidswell commenced by giving a full description of the methods and means followed in the diagnosis and recognition of the plague. The experience of the Public Health Department of Sydney was that when the first case of plague appeared it was successfully recognised, being fortunately a perfectly clear and straightforward one, and their subsequent experience was to the effect that whilst the great majority of cases could be diagnosed without hesitation they would now and then meet with one concerning which they could not form any decided opinion. It would, therefore, seem that the learnedly cautious attitude adopted by writers on plague was not only commendable from an academic standpoint but was also expressive of real practical difficulty, although this might, as in the epidemic at Sydney, be only of occasional occurrence. As a consequence of his experience Dr. Tidswell, for practical purposes, regarded plague in a way which if it never left him in doubt never led him into error; he mentally classified the cases into those which could be diagnosed off-hand and those which could not be safely diagnosed at all by purely clinical means. Some of the latter were cleared up by an appeal to bacteriology and some even that auxiliary failed to determine. Generally speaking, therefore, given a case presenting symptoms common to many acute fevers the only clinical manifestation which invested it with the specific character of plague was the existence of an acutely inflamed lymphatic gland in the groin, axilla, or neck. In the absence of a bubo the medical practitioner could be little more than suspicious or perhaps more or less convinced that the case was plague; the final adjudication if forthcoming at all was expressed by the bacteriologist or delivered only at the post-mortem table. With regard to the basis on which to form the suspicion just mentioned, Dr. Tidswell was inclined to think that in practice general indications were more to be depended upon than the elucidation of particular symptoms. Dr. Tidswell spent some time in emphasising the importance of recognising that the condition presented at any particular time by a plague patient could rarely be relied upon as a guide to the future progress of the illness. At nearly all stages up to established convalescence there was a liability to sudden and unexpected changes of serious or even fatal consequence. It was particularly in patients apparently slightly ill or progressing favourably that untoward complications with a fatal termination were apt to occur with startling abruptness, and Dr. Tidswell pointed out that the experience of the medical men in Sydney taught them to regard the issue of any case as uncertain until all constitutional symptoms had quite passed away. The case quoted by Dr. Tidswell in connexion with this point is such a striking example of the importance of this rule that it is worthy of record. The patient in question was a man who had been transferred from his house to an ambulance and from the ambulance to a launch upon a stretcher for conveyance under the charge of a trained attendant to the quarantine hospital. This man felt so far from ill that he absolutely refused to obey the nurse's order to remain lying down and sat up during the half-hour's run of the launch down the bay and appeared to be enjoying the trip. As the launch approached the landing jetty of the hospital the patient stood up, waved his arm, and dropped. The man was carried off the launch a corpse, and his death was doubtless due to failure of the heart consequent on the degeneration of its fibres occurring in plague.—Another extremely interesting contribution was a paper read by Mr. S. M. **Kaka**, medical officer of health of the City and Port of Karachi, the capital of Scinde. Mr. Kaka having exceptional opportunities of understanding the nature and extent of Hindu prejudices and native customs was enabled to illustrate his remarks by recording facts with which he had personal acquaintance. He related how the native, when removed to a hospital, believed he was taken away to be poisoned, how the sick bed of the plague-stricken man was surrounded by 30 or 40 relatives, how the native's practice of moving about houses with bare feet resulted in direct inoculation with the poison of plague, and how religious ceremonies compelled the mourners to remain with the corpse. Mr. Kaka, however, had one cheerful passage in his discourse, describing how the natives at Karachi had been educated up to taking kindly to the evacuation of infected districts, and the people having been thus educated formed in successive epidemics their own camps. It was not unusual to find something like 25,000 living in the camps, each sect in its own range of huts and supervised by responsible officers. Unfortunately, however, this preventive measure was not without its drawbacks because it was not possible to prevent the natives from taking their sick with them and as must naturally happen when large bodies of the people migrate disinfection of their clothing and other belongings was a hopeless task to undertake. Mr. Kaka, later informed the meeting that in regard to this latter point the people have learnt to destroy by fire for themselves whatever in their opinion had become infected.—A very instructive evening was concluded by a discussion, in which Dr. H. F. **Parsons**, Mr. **Shirley Murphy**, and Dr. R. T. **Hewlett** joined.

THE WAR IN SOUTH AFRICA.

There is still a good deal of enteric fever among the British troops serving in South Africa, as may be seen by an inspection of the returns of the sick and wounded, and it is to be feared that there will be a recrudescence of the disease during the hot weather. Enteric fever may be said to be endemic in the country, and the cause must have been sown broadcast during its late epidemic prevalence. Sufficient time has elapsed for the compilation of returns showing the numbers of those who have been attacked and who have died among the troops who had been inoculated as compared with those who had not. Some information as to the results of the comparison should soon be forthcoming and is anxiously awaited. Considering the number of troops that have gone out to South Africa, that for most of them it is the first year of their service there, and that so many of them were inoculated against typhoid fever on the voyage out, there should be an excellent basis for instituting a statistical comparison, especially as most of the troops were exposed to similar conditions.

Owing to the recent fighting in various directions which has taken place there has been a considerable augmentation of the list of wounds and casualties of a surgical nature. The wounded from General Clements's reverse at Nooitgedacht have all been brought to Pretoria and are doing well. The news of the increased activity of the Boers and their invasion of Cape Colony has come as a very disappointing surprise; still these occurrences cannot by themselves have any real effect on the ultimate issue. The facts remain as they were—namely, that we are in possession of the enemy's capital, that some 20,000 prisoners are in our hands, that Mr. Kruger, the late President of one State, has fled to Europe, that the late President of the other State is a fugitive, and that the seaboard of the Cape is open to us to replenish our supplies of men, food, and ammunition.

Where so much has been said about the past, present, and prospective aspects of this war we may, perhaps, be pardoned for referring to some of the impressions which we have derived from good information. We have talked to "all sorts and conditions of men"—regulars, volunteers, colonials, and medical officers—regarding this war. As might be expected, there is much variety of opinion (there is ample room for it) in regard to the events in South Africa; still these differences of opinion do not seem to be so great as might have been imagined. The impression which we have received from what we have heard is, perhaps, best expressed by saying that those who had the largest experience and apparently knew most about the subject said the least and were the least dogmatic in the expression of their views. Especially was this the case in the imputation of blame. With regard to one thing all agreed—namely, that only those who had actually seen the country and who had been present in the campaign were in a position to pronounce an opinion upon it or to estimate its difficulties. After all, what was the root of the whole matter? Unpreparedness on our part. Whereas the Boers had thoroughly matured their plans and were well prepared, we were not. But why should any ignorance or unpreparedness have existed on the part of the Government and the War Office at the beginning of the war? It is probable that, as a matter of fact, they were not altogether ignorant of the true state of things, although they were not, of course, informed to anything like the same extent that they were subsequently. To whatever political party the Government of this country may belong there is nothing which it strives so much to avoid as war, and we may be sure that no stone will be left unturned in order to avoid it. It must in fairness be admitted, we think, that the Government did really believe up to the last moment that war would be averted. Sir Redvers Buller was no doubt correct in having so emphatically stated recently that the Government did not at once send an adequate force to the Cape lest it might be possibly accused of having actually brought about the war.

ASYLUM REPORTS.

Lanark District Asylum, Hartwood (Annual Report for 1899).—The population of the asylum during the year was 634 and comprised 344 males and 290 females; 307 patients were admitted during the year; of these 177 were males and 130 females. Of these 132—viz., 73 males and 59 females—were not first admissions. Dr. A. Campbell Clark, the medical superintendent, states in his report that the admission-rate was much in excess of that of the previous year. "The condition, mental and physical, of many of those admitted was very unsatisfactory, indeed many were hopeless from the first." The fact that so many cases are certified because of brain failure in late middle age or old age accounts for the large proportion of such cases in the asylum's admissions. The number of cases discharged as recovered during the year amounted to 89—viz., 51 males and 38 females, a total of 14 per cent. on the average number resident. This is a low rate, "but when one takes into account the nature of the admissions, the many senile sick and moribund cases, it is not surprising. While 17 patients died within a month of admission only one patient recovered." The deaths during the year amounted to 71—viz., 50 males and 21 females, or 11·2 per cent. of the average population. Of the deaths 2 were due to general tuberculosis, 9 to general paralysis, 13 to cerebral softenings and hæmorrhages, and 16 to cardiac disease with complications. "The death-rate has been abnormally high owing to the large number of broken-down, senile, and moribund cases admitted. ...... Many cases come to us which (in the Glasgow district) would find their way as emergency cases into the infirmaries or the large poorhouse hospitals, and need not be certified as insane at all." Epidemics of influenza broke out in the spring and lasted till May, the lungs being affected seriously and frequently. Only one suicide occurred during the year, and the accidents have been slight and few.

The Asylum for Idiots, Earlswood, Red Hill, Surrey (Annual Report for 1899).—The average number of patients resident during the year was 546, and comprised 366 males and 180 females. During the year 60 patients were admitted, 53 of these being first admissions and seven being re-admissions. Dr. Charles Caldecott the medical superintendent, points out in his report that the name "Asylum for Idiots" hampers the institution in receiving patients, as so many of the parents think they only take "idiots," whereas children of imbecile and feeble-minded type are also accepted, and he strongly urges the board to seriously consider whether the title cannot be changed to some such one as "Training School for the Feeble-minded and Asylum for Idiots and Imbeciles," a title which would not only accurately designate the true nature of the institution but also reconcile parents to the idea of sending children for treatment and training. It is also recommended that the training period should be extended from five to seven years. During the year 51 patients were discharged as relieved, and of these 35 were males and 16 were females. 17 patients—viz, 10 males and 7 females—died during the year, or 3·1 per cent. of the average number resident, phthisis claiming a large number of victims. Some of the cases show a notable longevity. Thus there are two patients who have resided in the institution for over 50 years each, while there are 141 patients who have been inmates each for over 20 years. Outbreaks of scarlet fever and of influenza occurred during the year, keeping the general infirmary full all through the year. The board decided some time ago to have a small infectious block for such emergencies, but this has not yet been carried out, and Dr. Caldecott points out the extremely awkward predicament in which the institution would be placed should any epidemic of infectious disease arise among the inmates. Regarding the classification of the inmates on a medical and industrial basis Dr. Caldecott points out "that to allow the institution to do the greatest good, with no possible harm to our trainable pupils, we require the untrainable or custodial cases removed to a separate building which could come under the same administrative head. The various officials of the English idiot and imbecile institutions have been absolutely unanimous on this point." The work of the institution during the year has been arduous and conducted under many difficulties, the war in South Africa having claimed no less than 12 of the male staff who had been ordered to join the colours The causes of imbecility and idiocy among the admissions were as follows: 13 cases were due to heredity, 2 to fevers during infancy, 10 were attributed to convulsions during teething, and 14 to shock or ill-health of the mother during pregnancy; 10 were epileptic on admission. In 16 cases the causation could not be traced. The board of management were able last year to announce that the heavy debt of £7879 incurred in 1897 had been liquidated. This happy result was attained through the exceptionally large amount of legacies (over £17,000) received this year. The purely charitable income—viz., annual subscriptions and donations—has not been quite equal to that of 1898, but the falling off has probably been due to the national efforts made for the sufferers from the war.

London County Asylum, Claybury, Essex (Annual Report for 1899).—The average number of patients resident during the year was 2482 and comprised 1035 males and 1447 females. During the year 556 cases were admitted, and of these 291 were males and 265 were females. Of the 556 admissions only about one-half of the cases suffering from a first attack of insanity were received within three months of the onset of their disease. Dr. Robert Jones, the medical superintendent, states in his report that the earlier such cases come under treatment the greater is the chance of recovery. "The chances of recovery diminish considerably and progressively, as the time before commencing treatment increases in length. Insanity also is more likely to be fatal in direct proportion to the delay which has taken place before commencing treatment." Of insanity associated with senile decay only 10 per cent. were over 60 years of age, as against 18 per cent. during the previous year. General paralysis has been found in 11 per cent. of the male admissions and in nearly 4 per cent. of the female. "There has been a high percentage of insanity from alcohol, and more than double the number of women than men have been admitted suffering from *mania a potû*." It is also ascertained that women relapse into insanity from alcohol and are re-admitted with far greater frequency than men. Their weakened inhibition appears to be unable to withstand the slightest temptation, and Dr. Jones points out that the best treatment for such cases is that of long detention in inebriate homes, which naturally cannot apply to asylums from which patients are discharged when mentally fit. Previous attacks and hereditary influences were ascertained to be the most probable cause of insanity in 34 per cent. of the admissions. Several patients who were admitted had delusions that they were "hounded by Kruger's relatives" and that "Spion Kop" was hissed into their ears. During the year 197 patients were discharged as recovered, or 7 93 per cent. of the average number resident. Of these 197 recoveries 55 had been in residence from three to six months, 33 from six to nine months, 32 were under three months, while 31 were from one to two years The deaths during the year amounted to 265—viz, 130 males and 135 females—or 10 68 per cent. of the average number resident. Of the deaths 46 were due to general paralysis of the insane, 20 to cardiac valvular disease, 39 to pneumonia, and 21 to phthisis. Of the 21 patients who died from phthisis it is probable that 15 contracted the disease in the asylum, having been in residence over two years "Hitherto no special precautionary measures for isolating cases of phthisis have been adopted here, ... but the matter has been before the sub-committee. I suspect that phthisis is more frequent in asylums than statistics tend to demonstrate and that the tubercle bacillus may be present and unsuspected in cases of death which are certified to have been due to other causes." An outbreak of colitis has caused 33 deaths (16 males and 17 females), a proportion of over 12 per cent. of the total deaths. In July, 1899, all cases of colitis were isolated in the detached hospital, and the staff of the latter was increased by six attendants (male and female) on account of the extra nursing required. A female patient pregnant on admission was safely delivered of a daughter. Miss Margaret Orange, M.D. Brux, one of the assistant medical officers, received injuries from a patient and was granted leave of absence for six months on full pay.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6270 births and 3744 deaths were registered during the week ending Dec. 15th. The annual rate of mortality in these towns, which had been 18·0 and 17·7 per 1000 in the two preceding weeks, further declined last week to 16·8. In London the death-rate was equal to 16·5 per 1000, while it averaged 17 0 in the 32 large provincial towns. The lowest death-rates in these towns were 8 6 in Norwich, 11·2 in Oldham, 11·8 in Preston, and 11 9 in Croydon; the highest rates were 20 0 in Gateshead and in Liverpool, 21·3 in Bolton, 22·1 in Nottingham, and 22·2 in Manchester. The 3744 deaths in these towns included 328 which were referred to the principal zymotic diseases, against 356 and 363 in the two preceding weeks; of these, 77 resulted from diphtheria, 68 from whooping-cough, 58 from "fever" (principally enteric), 49 from measles, 42 from scarlet fever, and 34 from diarrhœa. No death from any of these diseases occurred last week in Norwich or in Huddersfield; in the other towns they caused the lowest death-rates in Plymouth, Cardiff, Halifax, and Gateshead, and the highest rates in Swansea, Nottingham, Bolton, Sheffield, and Sunderland. The greatest mortality from measles occurred in Swansea; from whooping-cough, in Nottingham, Sheffield, and Sunderland; from "fever" in Preston; and from diarrhœa in Burnley. The mortality from scarlet fever showed no marked excess in any of the large towns. The 77 deaths from diphtheria included 20 in London, 12 in Sheffield, six in Leeds, and six in Leicester. No fatal case of small-pox was registered last week in any of the 33 towns, and only one small-pox patient remained under treatment on Saturday last, Dec. 15th, in the Metropolitan Asylums hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2617, against 2727 and 2687 on the two preceding Saturdays; 255 new cases were admitted during the week, against 246, 279, and 259 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 436 and 400 in the two preceding weeks, further declined last week to 349, and were 97 below the corrected average. The causes of 42, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in sixteen other smaller towns. The largest proportions of uncertified deaths were registered in Leicester, Liverpool, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·7 and 20 7 per 1000 in the two preceding weeks, further declined to 19 3 during the week ending Dec. 15th, but showed an excess of 2·5 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16 6 in Leith and 18 1 in Edinburgh to 19 7 in Glasgow and in Greenock and 28·7 in Perth. The 596 deaths in these towns included 33 which were referred to whooping-cough, 16 to measles, 10 to diarrhœa, eight to scarlet fever, six to "fever," three to small-pox, and three to diphtheria. In all 79 deaths resulted from these principal zymotic diseases, against 89 and 87 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2·6 per 1000, which was 1·1 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of whooping-cough, which had been 42 and 31 in the two preceding weeks, rose again last week to 33, of which 27 occurred in Glasgow and three in Greenock. The deaths from measles, which had been eight, 12, and 15 in the three preceding weeks, further rose to 16 last week, and included nine in Aberdeen, four in Glasgow, and three in Edinburgh. The fatal cases of diarrhœa, which had been 20, 19, and 18 in the three preceding weeks, further declined last week to 10, of which four were registered in Glasgow and three in Aberdeen. The deaths from scarlet fever, which had been five and nine in the two preceding weeks, declined again to eight last week, and included four in Glasgow and two in Edinburgh. The deaths referred to different forms of "fever" which had been four in each of the two preceding weeks, increased last week to six, of which four occurred in Glasgow, where the three fatal cases of small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 160 and 151 in the two preceding weeks, further decreased last week to 136, and showed a decline of 36 from the number in the corresponding period of last year. The causes of 17, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·5 and 27·4 per 1000 in the two preceding weeks, declined again to 25·8 during the week ending Dec. 15th. During the past four weeks the death-rate in the city has averaged 26·0 per 1000, the rate during the same period being 17 3 in London and 19 7 in Edinburgh. The 173 deaths belonging to Dublin registered during the week under notice were 9 less than the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 11 in each of the two preceding weeks; of these, seven resulted from whooping-cough, two from diarrhœa, one from measles, one from scarlet fever, and one from "fever" These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 1·2 in London and 1·0 in Edinburgh. The deaths referred to whooping-cough, which had been six and four in the two preceding weeks, rose again last week to seven. The mortality both from "fever," and from diarrhœa was below that recorded in the preceding week. The 173 deaths in Dublin last week included 26 of infants under one year of age and 47 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, while those of elderly persons slightly exceeded the number in the preceding week. Eight inquest cases and four deaths from violence were registered, and 59, or more than a third, of the deaths occurred in public institutions. The causes of 10, or nearly 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1900.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10·0 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 6·0, 8·7, and 10·7 per 1000 respectively. The rates were considerably below the average in Paddington, St. George Hanover-square, St. Martin-in-the-Fields, Clerkenwell, St. Olave Southwark, and Lee; while they showed the largest excess in Hammersmith, Fulham, St. Pancras, Stoke Newington, Limehouse, and Poplar sanitary areas. Three cases of small-pox were notified in London last month, and belonged respectively to Fulham, Chelsea, and Islington sanitary areas. Two small-pox patients were admitted into the Metropolitan Asylums hospitals during the month, and both remained under treatment on Saturday, Dec. 1st. The prevalence of scarlet fever showed a slight diminution from that in the preceding month; among the various sanitary areas this disease was proportionally most prevalent in Hammersmith, Stoke Newington, Strand, Poplar, Greenwich, and Lewisham. The Metropolitan Asylums hospitals contained 2659 scarlet fever patients at the end of November, against 1657, 1899, and 2569 at the end of the three preceding months; the weekly admissions averaged 259, against 152, 215, and 314 in the three preceding months. The prevalence of diphtheria showed a decline from that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Fulham, Stoke Newington, Poplar, Limehouse, Newington, and Lewisham sanitary areas. There were 1524 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of November, against 1171, 1231, and 1458 at the end of the three preceding months; the weekly admissions averaged 185, against 142, 185, and 206 in the three preceding

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING NOVEMBER, 1900.

* Including 22 cases of membranous croup.

† Including deaths from membranous croup.

NOTE.—The changes made under the London Government Act (1899) are not taken into account until the commencement of next year.

months. The prevalence of enteric fever showed a continued increase over that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in St. James Westminster, St. Pancras, St. Luke, Limehouse, St. Saviour Southwark, and St. George Southwark. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 170, 329, and 444 at the end of the three preceding months, had declined again to 436 at the end of November; the weekly admissions averaged 61, against 32, 69, and 61 in the three preceding months. Erysipelas was proportionally most prevalent in Shoreditch, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, and Rotherhithe sanitary areas. The 29 cases of puerperal fever included three in Islington, three in Hackney, three in Wandsworth, two in Kensington, two in Fulham, two in St George-in-the-East, and two in Newington sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Dec. 1st the deaths of 5897 persons belonging to London were registered, equal to an annual rate of 16·8 per 1000, against 19·4, 16·5, and 15·3 per 1000 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 11·3 in Hampstead and in Stoke Newington, 12·1 in Lewisham, 12·3 in Plumstead, 13·2 in St. Martin-in-the-Fields, 13·3 in Battersea, and 13·4 in St. James Westminster; the highest rates were 24·5 in St. George-in-the-East, 25·9 in Holborn, 26·2 in St. Saviour Southwark, 26 8 in Limehouse, 27·6 in St. Luke, and 28 0 in St. George Southwark. During the four weeks of November 476 deaths were referred to the principal zymotic diseases; of these, one resulted from small-pox, 94 from measles, 33 from scarlet fever, 118 from diphtheria, 79 from whooping-cough, one from typhus fever, 89 from enteric fever, and 61 from diarrhœa. No death from any of these diseases occurred last month in Holborn, City of London, or St. Olave Southwark; in the other sanitary areas they caused the lowest death-rates in Hammersmith, Westminster, Hackney, Strand, Clerkenwell, and Lee; and the highest rates in Stoke Newington, St. Luke, Shoreditch, Limehouse, St. Saviour Southwark, St. George Southwark, and Bermondsey. The fatal case of small-pox was that of a person belonging to Islington sanitary area. The 94 deaths from measles showed a decline of 110 from the corrected average; this disease was proportionally most fatal in St. Luke, Shoreditch, Limehouse, St. Saviour Southwark, St. George Southwark, and Bermondsey. The fatal cases of scarlet fever were only 33, against an average of 86 in the corresponding periods of the 10 preceding years; the greatest proportional mortality from this disease occurred in Fulham, Marylebone, Whitechapel, Newington, Lambeth, and Wandsworth sanitary areas. The 118 deaths from diphtheria were 97 below the corrected average; among the various sanitary areas this disease was proportionally most fatal in Stoke Newington, St. Giles, St. George-in-the-East, Poplar, St. George Southwark, and Bermondsey. The 79 fatal cases of whooping-cough were 28 below the average number in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in Shoreditch, St. Saviour Southwark, St. George Southwark, Bermondsey, Rotherhithe, and Lambeth. The 90 deaths referred to "fever" were equal to the corrected average; among the various sanitary areas the "fever" death-rate was highest in Westminster, Hampstead, St. Luke, Limehouse, St. George Southwark, and Rotherhithe. The 61 fatal cases of diarrhœa were slightly below the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Fulham, St. James Westminster, Strand, Bethnal Green, and St. George-in-the-East. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during November was nearly 38 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 151 per 1000. The lowest rates of infant mortality were recorded in Stoke Newington, St. Giles, Strand, Lewisham, Lee, and Plumstead; and the highest rates in Westminster, St. Martin-in-the-Fields, Holborn, Shoreditch, St. Saviour Southwark, St. George Southwark, and Rotherhithe sanitary areas.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: J. O'B. Williams to the Royal Marines, Plymouth, and R. Bentham to the *Magnificent*. Surgeons: H. C. Adams, W. E. Gribbell, and H. V. Wells to the *Vivid*; L. Lindop, J. Whelan, and J. Verdon to the *Duke of Wellington*; C. L. W. Bunton to the *Forte*; S. Croneen to the *Raven*; and J. M. H. Conway, A. J. Sheldon, and C. R. Rickard to the *Wildfire*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel M. W. Kerin has arrived at Colchester for duty. Major S. O. Stuart is instructed to proceed to Woolwich for duty. Lieutenant P. C. Douglass has joined at Woolwich. Majors J. C. Weir and L. P. Mumby are appointed Sanitary Officers, Punjab Command. Lieutenant W. S. Crosthwaite is posted to the Station Hospital, Shorncliffe for duty.

The undermentioned surgeons-on-probation to be Lieutenants:—Henry James McGrigor, William Richard Power Goodwin, John Handfield Brunskill, Arthur Cameron Duffey, Arthur William Gibson, Charles Duncan Myles, Rochford Noel Hunt, Henry Edward Joseph Alphonsus Howley, Ralph Frankland Morris Fawcett, William Lawrence Steele, Hugh Allan Davidson, Thomas Finucane, John Weir West, William Riach, Herbert Raymond Bateman, Horace George Pinches, Thomas White, James Crawford Kennedy, Arthur Ruscombe Crane Parsons, John Burton Cautley, William Moore Bell Sparkes, Samuel Boylan Smith, Eyre William Powell, and John Jones.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major G. R. T. Phillips to be Surgeon-Lieutenant-Colonel. Surgeon-Captain Thomas W. J. Allen having resigned his appointment in the Volunteers ceases to belong to the Army Medical Reserve.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Captain Adam Robert Hamilton Oakley, from the 1st Volunteer Battalion the Essex Regiment, to be Surgeon-Captain. Captain William Vernor Sinclair, from the 3rd Volunteer Battalion the Devonshire Regiment, to be Surgeon-Lieutenant. Surgeon-Lieutenant William Edward Manderson Corbett, from the 2nd Volunteer Battalion the Devonshire Regiment, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Gloucestershire: Surgeon-Major J. H. Wathen resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. *Royal Engineers*: 1st London: The undermentioned officer resigns his commission: Surgeon-Captain S. R. Dyer. *Rifle*: 8th (Scottish) Volunteer Battalion the King's (Liverpool Regiment): Charles John Macalister, formerly Surgeon-Captain, 2nd Volunteer Battalion, to be Surgeon-Captain. 2nd Volunteer Battalion the East Surrey Regiment: Brigade-Surgeon-Lieutenant-Colonel E. Pocklington resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement, vacating thereby his appointment as Senior Medical Officer to the Surrey Volunteer Infantry Brigade. 2nd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): The undermentioned Surgeon-Lieutenants to be Surgeon-Captains: L. P. Demetriadi and H. W. Williams. 2nd Volunteer Battalion the Durham Light Infantry: William Bratton to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

Colonel W. H. Otter, Commander Royal Canadian Regiment, in a letter to Major-General the Hon. Herbert Eaton, the secretary of the Colonial Troops Entertainment Committee, has expressed his heartfelt appreciation and that of the non-commissioned officers and men of the Royal Canadian regiment for the care and kindness shown to them. The committee are much in need of further subscriptions. One of the principal firms in the city has promised £1000 and a nobleman has promised £500 towards the funds, conditionally on other subscriptions being received for equivalent amounts or something approaching them.

On Dec. 7th the Mayor of Cardiff (Mr. T. Andrews, J.P.) entertained Mr. Lynn Thomas, F.R.C.S. Eng., at a banquet on the occasion of his safe return from South Africa, and also to acknowledge the great services voluntarily rendered by him in connexion with the Welsh hospital. Amongst those present were Lieutenant-General Sir James Hills-Johnes, V.C., G.C.B., Dr. Edwards, and Canon Thompson. After the dinner the Mayor presented Mr. Lynn Thomas with a silver salver which bore an inscription recording the recipient's services in South Africa.—At a special meeting of the committee of the Cardiff *Infirmary held* on Dec. 14th the *resolution passed by the governor on* Dec. 7th requesting Mr. Lynn Thomas, F.R.C.S. Eng., to accept the full position of honorary surgeon to the institution in appreciation of the valuable services rendered by him in connexion with the Welsh Hospital in South Africa was unanimously confirmed on the motion of the chairman (Major-General Lee).

The *Canada* which is due at Southampton about Jan. 2nd has on board Lord and Lady Roberts and the Misses Roberts and the following members of the medical profession:—Indian Medical Service: Major W. R. Edwards. *Royal Army Medical Corps*: Major H. B. Mathias, Civil Surgeon C. Franks, and Civil Surgeon A. Ricketts. The following invalids are also on board:—Royal Army Medical Corps: Major E. M. Hassard, Captain H. W. H. O'Reilly, Lieutenant S. G. Butler, Lieutenant R. S. Rodger, and Civil Surgeon F. W. Robinson.

Civil Surgeon Englebach, reported missing at Nooitgedacht on *Dec.* 13th, was killed in action.

Civil Surgeon B. A. Nicoll left Cape Town for England in the *Aroca* on Dec. 9th.

The following officers have been discharged from hospital *to duty*: Major G. A. Wade, R.A.M.C., Civil Surgeons R. Williams, G. L. Hayden, Ed. H. Worth, A. Young, Lieutenant N. J. C. Rutherford, R.A.M.C., and Civil Surgeon D. W. Johnson.

Civil Surgeon R. M. Cowie, reported dangerously ill at Wynberg on Dec. 15th, is now reported to be improving.

A TRIBUTE TO MEDICAL GALLANTRY.

A Reuter's correspondent in a realistic account of the action in which Colonel Le Gallais was killed published in the *Times* of Dec. 17th concludes as follows: "It is not, luckily, an uncommon thing to chronicle the gallantry of the Medical Corps. Captain Surgeon Naismith behaved throughout the whole day with the utmost coolness. He tended the wounded wherever he found them, regardless of bullets, and apparently unconscious of them. Captain Newmarsh, an Australian doctor, volunteered to stay with the wounded at the farmhouse. The Boers behaved very kindly and put a sentry on the house with orders to allow no one to approach. When he left Captain Newmarsh presented them with some provisions in return for their kindness."

DEATHS IN THE SERVICES.

Surgeon-General George Vernon Currie, I.M.S., late 10th Bengal Lancers, recently at Eastbourne-terrace, Hyde Park, W., aged 72 years. He served in the Indian Mutiny campaign against the Mohmunds on the North-west Frontier in 1858, in the Eusofzai and Swat Expedition of 1866, and in the Afghan War of 1879.

Correspondence.

"Audi alteram partem."

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 15th, p. 1759, Mr. E. D. Marriott gives certain figures and draws a particular lesson from them, the lesson being that—"judged by results"—he has "brought the failure of the isolation hospital, so far as scarlet fever is concerned, to an absolute demonstration." Now, Sirs, I think, when the figures he has given are carefully examined they will be seen to prove no such "absolute demonstration." All his figures are taken from the "returns" of medical officers of health for some of the years between 1891 and 1898, some time during which period an epidemic of scarlet fever was prevalent in all the large towns of England. He also gives the "returns" for Nottingham and Bolton in detail from 1883 and 1879 respectively, until 1899, the former town commencing isolation in 1885 and the latter in 1884; and he claims that these "returns" supply the "most complete object lesson" that increase of scarlet fever followed the opening of isolation hospitals. Now, if the returns from these two towns be drawn up in the form of a chart, such as is given below, it will be seen that such is not the case, but that there has been a rise and fall in the number of scarlet fever notifications, which rise and fall takes place in well-known and recognised periodic waves, each wave occupying somewhere about 10 years.

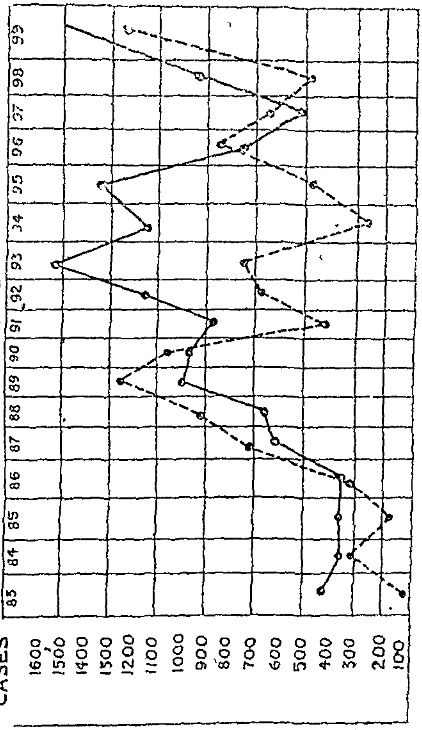

Chart showing the rise and fall of cases of scarlet fever notified in Nottingham (plain line) and Bolton (broken line).

Now, by comparison with the rises in the other large towns mentioned it will be seen that the maximum in them took place about the same time as in the two towns given as "object lessons." Fortunately for Mr. Marriott's deductions the towns taken to demonstrate the "complete object lesson" opened their isolation hospitals when the wave was at its lowest, and were consequently followed—not in the next year, however—by a rise. Mr. Marriott wishes to show that the rise was due to the aggregation of the cases; in fact, he says that "the opening of the hospital [referring to Bolton] was signalised by an increase in the number of notified cases too gradual to leave us in doubt as to the cause." I think that he misreads his information and thus draws a very incorrect lesson. If the towns named had delayed the opening of their hospitals for four or five years such openings would then have been followed by an immediate and considerable fall and then Mr. Marriott could not have deduced his "object lesson." Can he prove that if the Nottingham and Bolton hospitals had not been opened these rises would not have occurred, or that they would have been smaller? and how does he explain the fall which followed the rise? Would not the rises have been a good deal higher if those hospitals had not been opened? Were, in fact, the rises not due to natural and uninterpreted causes perfectly independent of aggregation?

Mr. Marriott further states that "discharged patients are *all* a source of danger." Some of them are decidedly dangerous, but certainly not all. The dangerous ones, from some 2 to 5 per cent., are so either in themselves or merely as carriers of infection from others. It seems to me that the danger does not prove in any way the failure of aggregation, as Mr. Marriott implies, but rather that we are yet unacquainted with the nature of scarlet fever infection and the manner of its conveyance by these dangerous individuals, for return cases occur amongst patients discharged early as well as amongst those detained for a lengthy period; amongst patients having discharges (nasal and aural) and such as have none; amongst those discharged from acute as well as from convalescent wards. Again, is the evidence absolute enough to prove that the phenomenon of return cases is entirely a hospital one? How long does a house remain a centre of infection after a patient has been removed to hospital? for I have known other patients admitted into hospital from the same house on the same day and immediately before the previous patient had been discharged.

Return cases are few—from 2 to 5 per cent. of the discharges. Now, if the other 95 to 98 per cent. of the cases notified were not removed to hospital would there have been no other infections from them? This supposition seems to me incredible.

All these are questions which will have to be discussed and determined in the near future, and if Mr. Marriott's letter sets such inquiries on foot he will have done some good, but the "object lesson" he endeavours to demonstrate from the figures he gives is, in my firm belief, fallacious.

I am, Sirs, yours faithfully,

Manchester, Dec. 16th, 1900. A. J. TONKIN, M.B. R.U.I.

"POISON IN BEER."

To the Editors of THE LANCET.

SIRS,—As there will be no opportunity of raising this question in Parliament for some time, will you allow me, on behalf of my fellow-Members and others interested in the Pure Beer movement, to offer a few observations upon the present aspect of affairs from our point of view?

We have now had an opportunity of questioning members of the Government whose departments are in some way or other supposed to have jurisdiction, and from the answers received it would appear that the duty of conducting an inquiry into the circumstances connected with the recent epidemic has devolved upon the Local Government Board. Here I may say that we are so far fortunate in having at the head of that department a man of undoubted courage and one who may be relied upon, once he is satisfied of his facts, to do his duty unflinchingly. We cannot help thinking, however, that it would have been more reassuring to the public mind if a strong expert committee, such as the Manchester Brewers' Association organised, had been immediately appointed by Her Majesty's Government, in which case they would no doubt have retained the services of the official analysts to the Home Office, both of whom are now members of the Brewers' Committee. In France such an epidemic as this would be at once investigated by the Council of Hygiene, or in Germany by the Imperial Board of Health.

In this country, wherever the interest of the beer-drinker crops up it is difficult to find under which thimble the pea really is, but to us it is very clear where the actual responsibility lies. When the advocates for a definition of beer withdrew their Bill in 1896 the Chancellor of the Exchequer promised to appoint a committee, which was subsequently instructed to report "whether legislation is required to prevent the use of deleterious substances in the manufacture of beer." The majority of this committee (a departmental not a parliamentary committee) reported that "the Treasury are empowered to prohibit the use in the manufacture of beer of any substance or liquor of a noxious or detrimental nature. It is the duty of the chemists employed in the Government Laboratory to keep a vigilant watch in this respect over all beer brewed and sold, and they have ample opportunities for so doing." Yesterday we were told by the Secretary to the Treasury that the power alluded to was conferred upon the Treasury by the Inland Revenue Act, but that "the duty of providing proper securities for the wholesomeness of beer, like other articles of food, is placed by law on the local authorities subject, if necessary, to the Local Government Board or Board of Agriculture," and that therefore "the Treasury had not exercised this power." A pretty puzzle this. Between the Treasury, the Inland Revenue chemists, the local authorities, the Local Government Board, and the Board of Agriculture, where is the beer-drinker?

Although the Inland Revenue authorities know what firms use substitutes they have resolutely declined to give that information to Parliament and the public. On this point the majority of the committee expressed their opinion that it would be "an inquisitorial interference with business of a rather invidious kind"; but as their report was practically a justification of the use of these substitutes, it is difficult to see how it would be "invidious" to state who used them. No, Sirs, the Inland Revenue officials consider it their duty to see that as much liquor as possible pays duty, and the brewers who do not confine themselves to malt and hops say that the public like the substitutes, although they have not sufficient confidence in their compounds to call them by any other name than "beer."

It is quite likely that the policy pursued by the Inland Revenue may yet have the opposite result to that anticipated. The present scare has already brought about a considerable diminution in the consumption of beer, to the consequent detriment of the revenue. We believe that the more people are satisfied as to the purity of beer, the more generally they will drink it and the more will the revenue be augmented. Therefore, to our minds, everything points to the desirability of an early enactment defining "beer," and extending to it the same principle that Parliament has already sanctioned with respect to other important articles of diet. If these objects are to be secured it will be necessary, unless the Government are wise enough to take the matter into their own hands, to have a powerful organisation in order to focus the great volume of public feeling which exists throughout the country and of which ample evidence is afforded by the stream of resolutions of public bodies, as well as private correspondents, which pours in upon me every day.

No one who has read the minority report of the committee above referred to can say that this calamity has come upon the Government and the people without warning. We only hope that the sickness and death amongst our fellow-countrymen in the North, sad as it is, will have the result of bringing about a much-needed reform, but this can never be effected until the masses of the people realise and impress unmistakably upon the Government how vitally their interests are concerned with the purity of the national beverage.—I am, Sirs, yours faithfully,

CUTHBERT QUILTER.

House of Commons, Dec. 14th, 1900.

A GERMAN CRITICISM OF THE PRESENT STATE OF OTOLOGY IN GREAT BRITAIN.

To the Editors of THE LANCET.

SIRS,—The debt of gratitude which we owe to our English colleagues, who were the first to promote the study of otology on a sound scientific basis, will always remain in our memory. Toynbee founded the pathological anatomy of the ear and was the first to build up those principles which stamped otology as a science. Nevertheless, his countrymen neglected to gather in the fruits of the seed he had sown and so the leadership of scientific progress in otology passed into the hands of other nations.

However, the growth of otological works in England during the last ten years points to the fact that fresh endeavours are being made to recover lost ground. Still, those who make a point of systematically reading the English literature are often astonished at the apparently almost complete ignorance of all foreign writings, and I really am unable to account for this remarkable fact. It may perhaps be due to their ignorance of foreign languages, so often noticeable in our English colleagues, which prevents them from making use of foreign literature, or perhaps owing to their extensive private practice they have not sufficient spare time to peruse the German scientific writings. This fault alone cannot help giving the experienced reader the impression that the work is not up to date. Many otological writings are published by the English press which no German journal would accept because their contents are already out of date, and many therapeutical suggestions are published as *new* which every aural surgeon in Germany has long been acquainted with. If our desire to enlighten our English colleagues on this question is to be of any practical value we must above all prove the accuracy of our assertions. In this I limit myself to a few striking examples. Although the question with regard to ligaturing the jugular vein in cases of sinus phlebitis ex otitide is still under discussion, yet it is generally acknowledged that for specified cases the ligaturing of the vena jugularis interna is an important step forward in the treatment of sinus thrombosis. Further, all German otologists are now unanimously of the opinion that in cases where the diagnosis of sinus thrombosis has been made with certainty the sinus should be laid open and the infected thrombus removed. To Zaufal (Prague) are we indebted for having suggested this operation. As long ago as 1880 he recommended the opening of the diseased sinus as well as the ligaturing of the vena jugularis interna,[1] and in 1884[2] he was the first to perform the operation, or at least to wash out and drain a sinus already opened by ulceration.

In 1886, six years after Zaufal, Horsley[3] suggested the same operative treatment, but without even mentioning Zaufal's name, showing that he was in complete ignorance of the well-known professor of otology in Prague. This operation performed two years later (1888) by Horsley himself ended fatally. That this operation has become popular through the favourable results obtained by our English colleagues, Lane[4] and Ballance,[5] has nothing to do with the question of priority.

As a further proof of the accuracy of the above stated assertions let us take Macewen's well-known book "Pyogenic Infective Diseases of the Brain and Spinal Cord, Meningitis, Abscess of the Brain, Infective Sinus Thrombosis," which was published in 1893, and was received in Germany not only by otologists but by general surgeons and neurologists as well with universal approbation. The large mass of carefully observed clinical material, the infinite pains taken in the working out of the anatomy, the almost too surprisingly successful results from operation which opened up a hitherto undreamed of field in the treatment of intracranial complications are tokens of the great scientific value of this book. Nevertheless, the book shows evidence of its author's very superficial knowledge of the German literature on the subject, only those writings translated into English being apparently known to him. Also the promise made in the preface to publish later an appendix of the literature on the subject has not yet been fulfilled. The fact that much is considered by Macewen as being *new* which in reality has long been known can only be explained by his lack of knowledge of the literature, and this is especially brought out in his description of the mastoid operation.

As regards the indications for this operation Macewen still holds the same views as Schwartze did 20 years before him. If he had referred to the above mentioned author he would have been aware that Schwartze had considerably modified his earlier views and that he now pointed out cases where, in opposition to the previous simple opening of the antrum, he recommended the so-called "radical" operation (*Totalaufmeisselung der Mittelohrraume*) as being more suitable and in which the healing would be more rapid. The operation which Macewen advocates is in many cases insufficient and has now become obsolete. The extensive and more recent literature on this subject which the introduction of the more radical methods of operation (Kuster, Zaufal, Stacke, &c.) gave rise to, and especially the chapter on "Operations" in Schwartze's book on the Diseases of the Ear (Schwartze's Handbook, Band ii., 1892), are, if we may judge from what he has written on the subject, apparently unknown to him.

The paper by Ballance above referred to shows the same want of familiarity with the current literature and may be taken as an example from the most recent publications to again point out the justness of my previous assertions. The title of this paper is as follows: "The Conduct of the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa with Special Reference to the Immediate Healing of the Cavity in the Bone left by the Operation by means of Epithelial Grafts."[6] The author describes in this paper the "radical" operation as a "description of my *own* plan of operation which has been developed from no inconsiderable experience." Instead of being contented with a single operation which has usually been considered sufficient he divides his operation into two parts—(1) the operation for the removal of the disease and (2) the operation for the healing of the wound. The description of *his* first operation differs only in unimportant details—*viz.*, the use of specially constructed "burrs" driven by an electro-motor—from the operation which has been in vogue in Germany during the last ten years. The second operation which is carried out, in the case of children after an interval of a week, in adults in two or three weeks, after the first operation consists in covering in the most painstaking manner the newly granulating surface of the bony cavity with "skin grafts." The only important difference in his method to that usually employed in Germany is that he makes a point of dividing the mastoid operation into two parts, whereas in this country the "skin-grafting" is only undertaken as a secondary operation in special cases. Although at the first cursory glance the favourable results of his cases seem to prove that his proposed method has met with success, still we do not feel disposed to attach very great weight to his statistics owing to the cases having been watched for much too short a period. Of what value is it when in a series of cases he only tells us that the discharge has ceased if nothing be said as regards the condition of the surface of the cavity, as to whether the cavity be covered with opaque or glistening epithelium, or whether on any part of its surface there be crusts or not? For any aural surgeon who has had any experience knows that the cessation of the discharge by no means guarantees a permanent cure.

I cannot, however, in principle agree with Ballance's proposed operation because it is not always possible to remove thoroughly all the diseased bone by operation. Quite apart from the fact that our hand is often stayed in operation in order not to damage the function of hearing or the facial nerve, and also that carious spots on the promontory, on the floor of the cavum tympani, and in the region of the bony Eustachian tube are not amenable to operation, it is often not possible for the eye to distinguish between the sound and diseased area of bone, so that later in the course of the after-treatment parts often prove to be diseased which at the time of operation were supposed to be healthy.

Now I come to the main point of the subject. Although the author in his description of the "first operation" makes no mention whatever, with the exception of a short reference to Stacke's paper, to the extensive German writings bearing on this subject, it may be that he is only giving his countrymen a paper on a subject well known to everyone. But his description of the "second operation" cannot help impressing the reader with the idea that the method of "skin-grafting" the mastoid cavity in order to accelerate the healing was devised by him.

He is evidently unaware that several German authors have prior claims to this method. Therefore I may as well point out here that, for instance, Siebenmann,[7] as early as 1893, recommended this method (*Thiersch's epithelial skin grafts*) after operating on cavities containing cholesteatoma, and that before this several others had already made the same experiment elsewhere. I think that the foregoing example will be sufficient to convince our English colleagues of the justness of my previous *remarks*. Our English-speaking colleagues on the other side of the Atlantic have been far quicker in obtaining knowledge and dexterity in theory and practice from the sources of scientific progress themselves, with what result can be seen from their recent literature, the excellence of which may be taken as a sure sign of their advancing scientific knowledge.

I am, Sirs, yours faithfully,
Professor Dr. Grunert.
Assistant Surgeon to the Clinic for Diseases of the Ear in the Royal University of Halle a/S (Professor H. Schwartze).

A NEW AND PROBABLE SOURCE OF ARSENIC IN BEER.

To the Editors of The Lancet.

Sirs,—My researches as to the source of arsenic in beer confirm those of Mr. Kirkby of Owens College—namely, that the greatest source is arsenicated sulphuric acid used in making glucose and invert sugar. There is, however, one possible and probable source of contamination of beer that I have not seen reported on. My attention was drawn to it by the fact that some of the arsenicated beers of Bacup were made from malt and hops only, no glucose or invert sugar being used. The brewers and analysts concerned were puzzled to account for it. The amount present was probably less than one grain of arsenic in 280,000. One brewer found that I had taken the first draw from the pump in the morning and suggested that the pipes and indiarubber tubing leading from the pumps to the barrel might be the cause. Samples of beer were taken from the wood or barrel and they were found to be absolutely free from arsenic by the most delicate tests known. It was clear, therefore, that the contamination must be after the beer left the barrel. I obtained a new pipe of the kind used in the trade and found arsenic present. I then obtained indiarubber tubing which had been used; arsenic was present in much larger quantity.

[6] London: H. K. Lewis. 1900.

[7] Berliner Klinische Wochenschrift, 1893, No. 1.

As regards the main cause of this arsenical poisoning epidemic, it is obvious that the amount of arsenic present in the rubber tubing used would not be of very serious account, as it is probably less than one part in 280,000; nevertheless, one can easily understand that beer having stood in the tubing all night, or for some considerable period, may be distinctly marred from this source. By Gutzeit's test there was distinct evidence of arsenic being present in both new and old indiarubber tubing, also in old and new lead piping. The old rubber tubing having been dissected into three layers, each was submitted separately to this test, also the layers together, and the results were compared. In old rubber tubing (1) the inner coat showed an appreciable quantity of arsenic easily detected (the beer passing into the tube was found to be arsenicated); (2) the middle coat or canvas layer gave the most marked result, arsenic being present in distinct quantity; and (3) the outer coat showed a very faint, almost inappreciable, quantity. On comparing the canvas layer or middle coat with the result of the three layers together it was quite clear that this coat was the most highly charged. *New rubber* tubing analysed similarly gave the following results: (1) the inner coat was practically free; (2) the middle coat again gave evidence of arsenic being present in somewhat similar quantities to those found in the old tubing; and (3) the outer coat gave distinct traces. On comparing the canvas coat with the three layers together the results again showed the middle coat to be the chief source of arsenic. The quantity used in the above investigations was one gramme.

I am, Sirs, yours faithfully,
Bacup, Dec. 19th, 1900. JOHN BROWN, M.D., D.P.H. Vict.

ARSENIC AND AERATED WATERS.

To the Editors of THE LANCET.

SIRS,—I referred in my communication to you *re* arsenic in beer[1] as to the possibility of aerated waters prepared from arseniated sulphuric acid being contaminated. I am now glad to be able to report that no trace of arsenic could be found after exhaustive analysis in specimens of soda water, hop ale, and lemonade submitted for examination, although an impure specimen of sulphuric acid had been used in their manufacture. A very faint trace of lead was found in the lemonade, probably derived from the citric acid used. I may add that the impure sulphuric acid was at once returned to the manufacturers.

I am, Sirs, yours faithfully,
A. H. BAMPTON, M.D. R.U.I.
Ilkley-in-Wharfedale, Dec. 15th, 1900.

"A RECENT DEVELOPMENT IN ADVERTISING."

To the Editors of THE LANCET.

SIRS,—First let me thank you for the excellent advertisement you have given to Craigside Hydro, Llandudno, free of charge, in your leaderette in the issue of THE LANCET of Dec. 15th, under the above heading. In the leaderette you have thought it necessary to condemn the method of advertising adopted by its directors, which method you describe as "evil," and moreover charge medical men who take advantage of the directors' invitation with sacrifice of self-respect.

I cannot help feeling that you have made these charges with a very slight knowledge of what you write about, probably without seeing the letter accompanying the coupon. I cannot think that you object to a hydropathic establishment advertising, otherwise you would not admit advertisements of hydros to your advertisement columns. Nor can I think that you object to directors of such institutions bringing their establishment to the notice of the medical profession, otherwise the *raison d'être* for your advertisement pages is abolished. I conclude, therefore that it is the suggestion that medical men should at the cost (in some cases considerable) of their railway fare only be invited to visit the establishment to which they are asked to entrust their patients for, it may be, a considerable time.

I enclose a copy of the letter which accompanied the coupon and from this you will see that it is a straightforward request to medical men to send their patients to this establishment. It would be unreasonable to expect a doctor to send a patient to an establishment with which he was unacquainted; surely, therefore, the fact that he may once in his lifetime visit it for three days free of charge to satisfy himself that it is a suitable place to which a patient may be sent can scarcely involve such charges as the delicately hinted "bribery" and "corruption" and badly expressed "loss of self-respect" which you make in your article. I should like to draw attention to the following sentence: "It says in effect 'We will pay you for a three days' holiday here, afterwards send your patients who will pay us.'" Owing to your lack of knowledge of facts I hope, and not to a desire to "score" by innuendo, you have missed the object of the letter. You should have said: "It says, in fact, 'Come and stay for three days without charge, and if you find things as you wish send your patients who will pay us, as we consider our establishment suitable for patients whom you wish to send to the seaside.'"

I am pleased to say that your prognosis as to the manner in which the advertisement would be received by the profession has already proved incorrect, as the directors have received numerous letters from doctors thanking them for the invitation and expressing the intention of the writers to avail themselves of the same, and have, moreover, cashed a considerable number of the coupons. It may be news to you, but it is nevertheless the fact, that it is not by any means an uncommon occurrence for medical men who write applying for charges for a holiday at a hydropathic establishment to ask for a reduction of terms in consequence of their profession and of their ability to recommend patients. As I said before, I enclose you the coupon and letter and trust you will be able to avail yourself of the directors' invitation.

I am, Sirs, yours faithfully,
Llandudno, Dec. 16th, 1900. J. MILES CHAMBERS,
Managing Director.

To the Editors of THE LANCET.

SIRS,—I write in the interests of mere justice (for I have no other interest in the matter) to protest against the tone of your annotation concerning the above. I for one can see no objection to the offer of entertaining medical men for three days in order to let them practically experience what manner of establishment is open for the reception of their patients if they please to recommend it. It is in no sense a constructive *bribe*, for no testimonial or *quid pro quo* is sought. If the medical man thinks the place worthy he can send his patients there—not unless. I have received advertisements from other establishments offering *commission* for sending patients, which is certainly objectionable; and from others offering to receive patients recommended by oneself at reduced charges, which might be open to abuse. But to the Craigside practice I cannot discern any honest objection. It is a perfectly fair and legitimate means of advertising—and without advertising how can such establishments become widely known? It is a guarantee to the public of the genuineness of the advantages of the establishment to submit it to such a practical test. To characterise it as an *implied bribe* to medical men is to lay the profession open to a most unworthy aspersion.

I am, Sirs, yours faithfully,
C. E. RICHMOND, F.R.C.S. Eng.
Manchester, Dec. 18th, 1900.

"NEW-LAID EGGS AND FRESH EGGS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 15th, p. 1758, I was pleased to read in the letter of Sir W. T. Gairdner about the system of his "very dear old relative" practised by her in greasing the new-laid eggs the instant they were laid with the practical result that the eggs remained fresh, by which means they were kept good for an indefinite period. Some 40 to 50 years ago my mother (God rest her soul) had a large number of hens, turkeys, and geese. The hens' eggs were brought in by one of the dairymaids when laid and they were "buttered." The large number of eggs that accumulated induced my mother to add to her "pin money" by selling them. Her buyers came, but though offered the buttered eggs they declined them as "not saleable." The result was that the eggs for home consumption were buttered, but those for sale were not. I fear, then, from this experience that if buyers of eggs are of the same opinion now as when my dear mother had to do with them the new-laid buttered eggs would not be acceptable to the trade, though much the public would lose in their freshness. The market and the middleman trader would have to be trained to the knowledge to induce a sale of preserved new-laid eggs to the public. If the "system" could only be promoted by poultry-farmers in general and adopted, what blessings would be given by the housekeepers and housewives of the metropolis and lodging-house boarders in having an egg for breakfast that was eatable.

"KIRKES' PHYSIOLOGY AND AMERICAN PIRACY."

To the Editors of THE LANCET.

SIRS,—Not having seen the letter of Mr. John Murray upon the subject, Professor Halliburton's communication in THE LANCET of Dec. 15th, 1900, p. 1761, was the first intimation to me that my name continues to appear upon the title-page of what may be called an *unauthorised edition* of Kirkes' Handbook of Physiology published in America, as joint editor with (the late) Mr. Morrant Baker. The well-informed reviewer of the *Boston Medical and Surgical Journal*, quoted by Professor Halliburton, gives a pretty accurate account of the history of the book in question. The first edition of Kirkes' Physiology was brought out in 1848 by Dr. Kirkes, assisted by Mr., afterwards Sir James, Paget, and these names appeared upon the title-page, I think, until 1869 when Mr. Morrant Baker edited the sixth edition. Mr. Baker continued to be sole editor until 1880 when I assisted him in bringing out the tenth edition. The book continued under our joint editorship until 1892 when the thirteenth edition was published; this was revised in 1894 and was, according to the preface, to be looked upon "in certain respects as a new edition." As far as I can recollect this revision was done by me. After the issue of this revised edition Mr. Morrant Baker and I ceased to be editors—the former in consequence of failing health and I because I had given up the teaching of physiology. The next edition was edited by Professor Halliburton and was to a large extent a new book with a complete rearrangement of the subjects and a much enlarged scope. The editor and the publisher were certainly justified in looking upon the fourteenth edition, therefore, as practically a new work upon physiology. Perhaps it would have been better if the old title had been given up, but there were, no doubt, cogent reasons against this. Since 1894, then, neither Mr. Morrant Baker (whose lamented death occurred in 1896) nor I have had anything whatever to do with the editing of "Kirkes' Handbook" and the continued use of our names in this connexion is a most unwarranted and unjustifiable proceeding.

I am, Sirs, your faithfully,
Queen Anne-street, W., Dec. 18th, 1900. VINCENT D. HARRIS.

"MERCANTILE MARINE MEDICAL OFFICERS."

To the Editors of THE LANCET.

SIRS,—There is an interesting letter in THE LANCET of Dec. 1st from your Paris correspondent dealing with, *inter alia*, mercantile marine medical officers. The perusal of this note and reading in the *Daily Telegraph* of Dec. 13th Admiral Hopkins's "Hints on the Navy of the New Century" reminded me that some few years ago I advocated the necessity of a medical adviser at the Board of Trade where just such matters as your correspondent alludes to should be dealt with, as well as others of a cognate character, by a specialist instead of the ordinary laymen. At that time you, Sirs, deemed my proposition "rather a large order." Perhaps the subject might now be worthy of reconsideration. And as there is a new President at the office the coming session of Parliament would be a favourable time to induct an official medical head at the Board following on the lines of the suggestion of Admiral Hopkins for the appointment of a flag officer at the Admiralty.

There are many measures in regard to the office of ship's surgeon and the conduct of affairs connected with that position requiring improvement, and notably the clearing of tramp steamers and short ships, *without inspection*, going long voyages, sometimes with incompetent men, and almost invariably ill-provided with medicines and instruments. The receiving and tabulating of medical reports of the diseases treated on board as well as those noted at different places of call—attention to the eyes of the ship—these and other strictly professional work in the interests of the sea-borne population as well as for the dwellers on land would well repay the expense of such an official. I simply throw out these suggestions in the hope, Sirs, that if you think favourably of them they may have the benefit of the powerful advocacy of THE LANCET in your own way.

I am, Sirs, yours faithfully,
R. A. CALDWELL.

Bournemouth, Dec. 17th, 1900.

THE RATING OF HOSPITALS.

To the Editors of THE LANCET.

SIRS,—With reference to the question I asked in the House of Commons last Friday, as to relieving hospitals and kindred institutions from the burden of paying rates, the following reply was given me by the Government:—

> I beg to inform my honourable friend that the matter is one of considerable difficulty and forms part of the subject now under the consideration of the Royal Commission on Local Taxation. I cannot at present give any promise as to its being dealt with by the Government.

For your information you may be interested to know that I shall not relax my efforts in the direction of the subject-matter of my question

I am, Sirs, yours faithfully,
Dec 20th, 1900. FRED. HORNER.

"THE TREATMENT OF MALARIA BY HOMŒOPATHIC MEASURES."

To the Editors of THE LANCET.

SIRS,—It is only two days ago that my attention was drawn to your article on "Malaria and Homœopathy" in your issue of Nov. 24th, and to the letter from my father, with your peculiar "editoral note" appended, which appeared in your succeeding issue. Your "note" provides a really interesting study, as it shows how uncontrollable temper and sense are not found at the same time in the same individual. Your quibbling as regards "qualified homœopath," is not only puerile, but utterly false.

Homœopathy is merely a higher branch of the therapeutics (?) [The query is Dr. Hayward's—ED. L.] taught at all our universities. Following out your argument, there are no "qualified nerve specialists," "qualified medical electricians," or "qualified serum therapists," as each of these departments is a higher development of its subject as taught in the universities. Not one of them was included either in the examination or curriculum, when you or I obtained our diplomas; although they have each (most decidedly including homœopathy—but in this case mystifying the source) since been more and more incorporated in the teaching of each of our colleges. All the most honoured men in our profession are therefore, according to your idea, "unqualified" in their special branch, an opinion which even you dare not put into print. I sympathise with you in the very unfortunate "analogy" you use, but consider that your execrable taste in using it fully merits the recoil it possesses. It is difficult to follow your analogy between honourable medical men—though homœopaths—and the characters you mention, but one is at once struck by the amazingly close resemblance between an editor who uses falsehood and mud to besmirch honourable opponents and another character who did the same thing—Pigot—and who is naturally suggested by your examples, but whose villany was of a distinctly meaner type than theirs.

I am sorry for the honourable profession which has to regard you in your official capacity as some sort of a figure-head when it sees you stooping to the gutter to grab the most unsavoury filth you can find so as to throw it at men as honourable as any others in the profession, men who have had the same medical training as yourself, who have satisfied the same examiners, and who have obtained at least as good diplomas as you yourself can hold. And after throwing the mud, with your hands still reeking of the gutter-filth, you "shut down" your columns so as to preclude the possibility of any protest from the gentlemen you have tried to vilify, or from honourable men on your own side who might desire to remonstrate with you.

I am afraid it is too much to expect you to re-open your columns so as to publish this letter, but if you could see your way to re-considering your decision I am sure it would give pleasure to your readers, for you know gentlemen are always pleased to see a gutter-snipe thrashed by one of the respectable people whose clothes he has attempted to dirty, even when—as in this case—he has only succeeded in soiling his own hands without in any way tarnishing the lustre of the object of his attack. I do not think the general profession will be glad to find that they have entrusted the management of an old and—excepting as regards the "editorial columns and notes"—a still honoured journal, to a man who, while having no pretence to gentlemanly feelings, mistakes falsehood and vituperation for the intelligence which should be as necessary as gentility in anyone managing such a property. However, so that some at least of the profession may be satisfied that your footnote "cannot give any more space to this matter.—ED. L.," has not stifled all protest, I am sending copies of this letter to two other medical journals, in which not only is the honour of the entire profession carefully guarded, but where gentlemanly conduct controls not only the outside contributions and advertisements, but—which differentiates them from your journal—in which it also regulates the editorial columns and comments.

I am, yours truly,
CHARLES W. HAYWARD, Barrister-at law, M.D., C.M., D.P.H., M.R.C.S., L.R.C.P.
Liverpool, Dec. 14th, 1900.

*** Dr. Hayward asks for the publication of his letter. Here it is.—ED. L.

"INFAMOUS."

To the Editors of THE LANCET.

SIRS,—Your report of the proceedings of the General Medical Council in its decision in the case of the Birmingham Consultative Institute cannot fail to give rise to a feeling of insecurity amongst members of the profession who hold public appointments. It would greatly tend to the public advantage if the Council would condescend to explain the subtleties which must lie beneath the surface of their decision of last week.

Why should it be "infamous" for a medical man's name to be printed on the prospectus of a company who have elected him as their medical officer, whilst at the same time the names of hundreds of medical men, bearing office in hospitals, insurance companies, medical clubs, &c., are scattered broadcast over the country in thousands of hospital reports, prospectuses, &c., with impunity? Again, the hydropathic institutions of this country advertise the name of their medical officer in pamphlet and poster. Is it not time that the General Medical Council, in addition to its other important duties, should revise the wording of their verdicts?

The word "infamous" means "having a reputation of the worst kind; publicly branded with odium for vice or guilt; base, scandalous, and notoriously vile; held in abhorrence; branded with infamy by conviction of a crime." It will be interesting if the Council will deign to point out which of the foregoing definitions apply to the Birmingham consultant. If "infamous" is a term to be employed as the official utterance against alleged advertising of a company's officer, why is not every holder of a public office equally "infamous"? Our public officer of health—a most worthy soul—is "infamous" under this ruling every week. Again, may I ask what is the proper term to employ in speaking of a medical man found guilty of criminal abortion?

I am, Sirs, yours faithfully,
Dec. 9th, 1900. A HOSPITAL SURGEON.

"THE LIABILITY OF THE BREWER IN THE RECENT EPIDEMIC OF PERIPHERAL NEURITIS."

To the Editors of THE LANCET.

SIRS,—The writer of the leading article in THE LANCET of Dec. 15th on the legal aspects of the recent epidemic of peripheral neuritis might have cited in support of his contentions cases which have attracted notice recently, such as the action of Smith *v.* the Inns of Court Hotel, in which it was alleged that guests had been poisoned by food eaten in the hotel; or an action which excited some amusement in 1896, brought by a plaintiff who claimed to have suffered from drinking beer out of a bottle containing a dead mouse. It will be found, I believe, that each of these cases turned on the question whether there had been negligence, and that it was not said in either that there was any implied warranty that the food or drink was fit for the purpose for which it was sold. From analogy thus supplied it seems clear, therefore, that any claims that may arise out of the epidemic will resolve themselves into the question whether the brewers were negligent.

Now neither the manufacture of glucose nor that of sulphuric acid is in the nature of a trade secret or an obscure scientific process. "Glucose in commerce = the sugar syrup obtained by the conversion of starch into sugar by sulphuric acid." "The sulphuric acid of commerce is never pure, but may contain lead sulphate, arsenic, and other impurities." These are not extracts from even a text-book on chemistry; I find them in the Century Dictionary under the words "glucose" and "sulphuric acid." On the other hand, the extent to which glucose and "invert" sugar are used in brewing, their sources, the prices paid for them, and the elements influencing such prices are matters intimately concerning individual brewers and are not easily scrutinised or controlled by others.

It seems, therefore, to me that there will be evidence that the brewers might have known, and must have known, that the chemical preparations they used were liable to contain arsenic or that they had no business to use them if they knew nothing about them. That knowing they might contain arsenic they ought to have analysed them in order to ascertain that they were pure, and that their neglecting to do so will be evidence of negligence on their part. You have in your columns shown the kind of scientific evidence at the disposal of plaintiffs and the evidence to prove that the negligence of the brewers was the cause of suffering and death to customers in public-houses owned by them for the exclusive sale of their own beers, and it further seems probable that juries will not be inclined to spare them. The precise evidence that will connect each case with the beer of the particular brewer will be a matter for the consideration of the individual litigant; the probable scope and general character of the case to be presented by those who have themselves been poisoned or who claim because they have lost relatives upon whom they depended you have pretty clearly indicated.

I am, Sirs, yours faithfully,
Dec. 19th, 1900. M. A.

P.S.—It is now stated that certain malts have been found to contain arsenic. Whether they do so owing to some new or secret process in their preparation has not yet been shown. It is, however, clear that brewers' chemists will have to master the details of the preparation of all materials that brewers use and analyse with a view to detecting all dangerous ingredients that known processes of manufacture are likely to introduce into them.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Bogus American Diplomas in India.—Typhoid Fever and the Water supply of Rangoon.—The Water-supply of Calcutta.—The Plague in India.—The "Barefoot Theory" of Plague Inoculation.

INDIA has apparently been a good market for the sale of bogus diplomas to native medical practitioners, for the Government has found it advisable to warn the public against certain American degrees. In a country like India, where there is no medical registration of any kind and where any knave can assume any title he likes, such a warning was especially necessary. There are certain persons in this country who are known to practise on these bogus degrees. It is therefore gratifying to find that action has been successfully taken in Chicago, and that one practitioner in Calcutta and another in Bombay have had their negotiations for these degrees cut short. Not much good can be accomplished, however, so long as the crowds of native untrained men are permitted to impose on their credulous fellow-countrymen.

In consequence of a severe outbreak of typhoid fever in Rangoon Major Davis was appointed by the local government to inquire into the condition of the water-supply. The result is a severe condemnation of the water from the standpipes, wells, and royal lakes. Of the latter Major Davis says: "The physical characteristics were so bad that I think it unfit for drinking. ...... The lake is also obviously liable to contamination." It appears that the causes of contamination are the deposits of manure on the land of Dalhousie Park for gardening purposes and the absence of sanitary precautions to prevent pollution by the large assemblage of low-class Burmans and other natives on the shores of the royal lake during the week's celebration of Burmese aquatic sports. In these days of advanced sanitation it is astonishing that the authorities should have allowed these things to exist. As a remedy the health officer advocates the hurrying on of the water scheme at Thamaing.

The city of Calcutta is also very improperly supplied with water. For drinking purposes the water is taken from the Hoogly several miles up the river and then filtered, but the supply is turned on only twice a day for a few hours. The consequence is that the natives largely use dirty pond water and equally dirty well water. The water used for the roads is the water from the river unfiltered. It is satisfactory to hear that a change is contemplated. A visit of certain corporation officials has been made to the filtering grounds and it is said that an improvement both in the quantity and quality of the water is promised. The city is also to have a continuous supply of filtered water. The pressure in the mains will also be increased, so that water may rise to the second, or even to the third, storey. At present it barely reaches the first. I find it reported that the commissioners have stopped the grazing of cattle in the grounds. Here, again, one cannot help expressing astonishment that such a thing should have been permitted. Calcutta has been described as the home of cholera. It is obvious, however, that the disease cannot be eradicated so long as the natives are permitted to use the numerous sewage-polluted ponds and wells.

The return of deaths from plague throughout India during the past week shows that the epidemic is not on the increase. There were recorded 1939 deaths as compared with 2192 for the preceding seven days and with 2080 for the corresponding week last year. The Mysore State is chiefly affected, but Calcutta, Monghyr, Saran, Patna, and Gaya in the Bengal Presidency continue to return double and treble figures Most of the deaths from plague in Calcutta are now returned as suspicious, but anyone acquainted with the facts can easily read between the lines. As the mortality in Calcutta as well as in Bombay keeps unusually and unexplainedly high it is very probable that there is more plague existing than is reported. I am pleased to record that plague has now again almost disappeared from the Punjab. In Bombay city there has been a slight increase over the previous returns.

The port health officer of Bombay, in his report for 1899, expresses himself very decidedly on the means of infection in plague as follows: "The majority of plague cases in the East contract the disease by inoculation through cracks, fissures, or ulcers on the feet, as the large majority of the population go barefoot." He goes on to express the opinion that "as long as plague in the East is confined to the bubonic type the people at European ports, and the other ports where the population wear boots and shoes, will not suffer from the disease in an epidemic form." The great care which is taken at the Bombay port against the spread of plague is probably the explanation why the disease has not been readily conveyed to other places. The "bare-foot theory" is open to question seeing that groin buboes are of common occurrence amongst Europeans and others who wear boots.

A further decrease of 142,135 persons in receipt of famine relief is recorded for this week. There are still 173 161 persons on relief works, the remainder receiving gratuitous relief. The various Native States have 59,573 persons on relief.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Peripheral Neuritis.

THERE have been 30 cases of peripheral neuritis in the Birkenhead Workhouse hospital since the middle of October. A coroner's inquest was held a few days ago in Birkenhead touching the death of a female who was suspected of having died from arsenical poisoning. Mr. G. S. Stansfield, the medical officer of the Birkenhead Workhouse, attributed the death to peripheral neuritis caused by arsenic or some other irritant poison. The inquest was adjourned for a fortnight to enable a thorough analysis to be made. In the Liverpool Workhouse several cases of peripheral neuritis are under treatment.

Death of Henry Greenwood Rawdon, M.D. St. And.

The news of the unexpected death of Dr. H. G. Rawdon at Elstree, Hertfordshire, was received by his numerous friends in Liverpool with great regret. Dr. Rawdon received his medical education at the old Liverpool School of Medicine and at Guy's Hospital, becoming a Member of the Royal College of Surgeons of England in 1858. Later he graduated as M.D. at the University of St. Andrews, and became a Fellow of the Royal College of Surgeons of Edinburgh in 1885. Dr. Rawdon was an excellent surgeon, his reputation being very high at the Liverpool Infirmary for Children (where he held the post of honorary surgeon for a number of years) owing to his successful and original operations for the repair of hare-lip and cleft palate. Upon his retirement from the Infirmary for Children he was appointed honorary surgeon at the Royal Southern Hospital. He retired from practice upwards of two years ago and removed to Elstree in Hertfordshire, devoting himself to rural occupations, which possessed a great charm for him. Dr. Rawdon had the misfortune to lose his wife 12 months ago, and his grief probably hastened his decease, which was due to apoplexy. He was in his sixty-fourth year and leaves no issue. Dr. Rawdon was descended from an old Yorkshire family, some of whose members served in the Parliamentary army during the Civil War in the reign of Charles I.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh: the Morison Lectures.

AT the annual meeting of the Royal College of Physicians of Edinburgh, held on Dec. 6th, the following Fellows were elected office-bearers of the College:—President: Dr. Thomas Richard Fraser. Vice-President: Dr. James Andrew. Council: Dr. J Wyllie, Sir John Batty Tuke, Dr. T. S. Clouston, Dr. G. A Gibson, and Dr. D. Berry Hart, along with the President and Vice-President.—The Morison Lectures were this year delivered by Dr. G. W. Balfour. The first lecture was delivered on Dec 4th in the hall of the Royal College of Physicians of Edinburgh, Dr. Andrew, President of the College, being in the chair. The title of the lectures was "On the Borderland," and in his first lecture Dr. Balfour discussed the many instances in history of persons who, judged by modern ideas, would be considered more or less insane, but who in their own time exerted a great and important influence on the nations among whom they lived. Quoting Dryden's dictum that "great wit to madness sure is near allied," he referred to the hallucinations of Socrates, the strange story of Joan of Arc, and the career of Mahomet, whom the lecturer held to be even more unmistakably insane than Joan of Arc. Turning to the realm of literature Dr. Balfour showed that many of the noblest works in literature had been produced by men who dwelt on the borderland, as examples of whom he cited Jonathan Swift and William Cowper. He also demonstrated that persons who might be classed in that category were often distinguished by remarkable activity of mind and body. The second lecture was delivered on Dec. 11th, Professor T. R. Fraser, the new President of the College, being in the chair. Dr. Balfour in continuing his subject dealt with what he called the epidemic insanities which had from time to time swept over the world. Examples of epidemic insanities were seen chiefly in the Middle Ages, though even in their own time there had been thought-waves of insanity which had only been noticed when criticised by another age. The most outstanding example was the occurrence of the Crusades. These were aroused by Peter the Hermit, being an attempt to drive the Mahomedans from the Holy Land, and they culminated in the tragedy of the Children's Crusades. The Crusades had left their influence on the world: they caused the breaking-up of feudalism and gave an impulse to commerce; moreover, by bringing leaders of men into closer contact with the Church they had brought about a closer scrutiny of the Papal system and paved the way for the Reformation. The Turk still ruled in Palestine, but Europe had benefited by the Crusades. No other epidemic of insanity, however, had been of advantage to the world. Dr. Balfour then referred to the pandemic dancing mania which appeared about the end of the fourteenth century and spread over Europe for 200 years. This choreiform insanity was finally put an end to by the Thirty Years' War. A remarkable form of epidemic insanity had occurred in this century—namely, table-turning, table-talking, and thought-reading. In 1851 there had been an epidemic of mesmeric mania which had left many enfeebled bodies and minds. Hypnotism had not been able to hold its place as a method of treatment and had now passed out of the region of medicine. Another form of insanity which had existed in all times, but which was more endemic than epidemic, was spiritualism. No single fact of any importance had been revealed by those calling themselves spiritualists. In conclusion Dr. Balfour drew the following lessons: 1. Insanity was a disease of which no one need be ashamed. It was a disease of the brain, not of the intellect, and might occur in persons possessing the finest minds. 2. As the object of all education was to control the emotions, so any excitement which tended to weaken the will and emancipate the lower part of the being was to be avoided. At the conclusion of the lecture Professor Fraser expressed thanks to Dr. Balfour in the name of the College. At both lectures there was a large attendance of ladies and gentlemen.

The Edinburgh Hospital and Dispensary for Women and Children.

On Dec. 10th the annual meeting of the friends of the Edinburgh Hospital and Dispensary for Women and Children was held in the Society of Arts Hall, George-street, Mrs. Steel, wife of the Lord Provost, being in the chair. This hospital has recently entered on a new phase of its existence, having been transferred from Grove-street to Bruntsfield Lodge. The new hospital is very well equipped and is, moreover, a home-like and cheerful building. Since it was opened some months ago many serious cases have been treated in its wards which could not have been undertaken in the Grove-street days. The medical officers hope in the coming year to work a similar reformation in the dispensary department which is still stationed in Grove-street. Among those who took part in the meeting were Lady Chalmers, Dr. Beatrice Russell, Dr. Emily Thomson, Dr. George W. Balfour, and Sir A. Christison.

Queen Victoria Jubilee Institute for Nurses.

The annual meeting of the subscribers to the Scottish Branch of the Queen Victoria Jubilee Institute for Nurses was held in the Training Home, Castle-terrace, Edinburgh, on Dec. 11th, Sheriff Guthrie, Q.C., being in the chair. During the past year 35 nurses completed their training as Queen's nurses in Edinburgh, while 13 nurses completed their training in the smaller training homes in other towns. Since the opening of the institute 271 nurses have been trained. There are now 199 Queen's nurses in Scotland working under 111 associations. Additional pecuniary assistance is much needed as the committee contemplate in the future trying to send nurses to districts where the people are too poor to support the nurses.

Appointment for the Medical Officer of Health of Leith.

Dr. W. Leslie Mackenzie, medical officer of health of Leith, has been appointed Inspector to the Local Government Board and has therefore resigned his post as medical officer of health of Leith. The resignation took effect on Dec. 15th and a successor to Dr. Mackenzie is to be advertised for at a salary of £400 per annum.

Dr. Alexander Edington on Malaria.

At last week's meeting of the Glasgow Philosophical Society Dr. Edington, director of the bacteriological institute of Cape Colony, gave an account of his nine years' work in South Africa. He dealt chiefly with the questions of "horse sickness," rinderpest, and Texas fever, referring to the striking success which had attended the practice of prophylactic immunisation by bacteriological methods, particularly in rinderpest. In passing he made an interesting reference to malarial fever. While giving his assent to the mosquito theory he warned his audience not to assume that this was the only way in which malaria may be acquired by the human subject, and in support of this warning he quoted the fact that while in Rhodesia mosquitoes were always present malarial fever prevailed only during three months of the year; and as evidence against the view that the anopheles host must have previously bitten a human being who was the subject of malaria he referred to the case of four young men who went hunting in an absolutely uninhabited district, three of whom died in a short time from malignant malaria, while the fourth was barely able to struggle home.

Glasgow Main Drainage.

The city engineer has issued a long and valuable memorandum on the progress of these works and the applicability of the bacterial method of purification of Glasgow sewage. Experimental plant for testing the bacterial method of dealing with sewage had been set down in the east end of the city, this experiment being the outcome of a report published by a committee which visited the bacterial sewage tank at Manchester, in which report the effluent is spoken of as being satisfactory, while "an enormous quantity of sludge which would otherwise accumulate is destroyed in this way." The most recent report from Manchester, however, shows that 4000 tons of putrid sludge had accumulated in this tank and was with difficulty taken out to sea, as the gases evolved caused the sludge to froth up over the valves on to the deck of the sludge steamer. In the experimental tank at Glasgow also the effluent is all that could be desired, but there is already evidence that sludge is collecting in the open septic tank. The cost of the proposed works for the bacterial treatment of sewage, moreover, puts the plan out of court as a practical scheme; in round figures it amounts, for the purposes of a city like Glasgow, to £1,500,000 for plant alone, with, further, the cost of 80 additional acres of land required for such plant. This and the large and at present incalculable working expenses and the cost of disposing of sludge form prohibitive obstacles to the scheme. Against this the cost of the precipitation plant is put at only £150,000 and the space required at 22 acres. All this refers of course only to the sewage plant at Dalmuir and not to the many miles of sewers required to connect the city with these works.

Glasgow Victoria Infirmary.

The annual report of this institution includes an appreciative reference to the late Sir Renny Watson who was for many years chairman of the infirmary. It also announces the completion of the nurses' home and gives the usual statistics, which show a generally satisfactory state of affairs, including the financial department. The Lord Provost, who presided, moved the adoption of the report and in his speech he argued against the suggestion that the infirmaries should be kept up by the public rates rather than, as at present, be dependant on private liberality. One of the most interesting features of the meeting was a proposal to place two ladies on the board of directors. A similar proposal has been adopted in connexion with the other large general infirmaries in Glasgow, but in spite of this precedent the supporters of the Victoria Infirmary would not be convinced and, somewhat ungallantly, placed the ladies at the bottom of the poll.

Glasgow University.

At the December meeting of the University Court the secretary read a letter from Dr. Thomas Reid resigning his appointment as university lecturer on diseases of the eye. The Court accepted the resignation and resolved to record in the minutes an expression of regret at the loss of Dr. Reid's services. Dr. Reid has held the lectureship for more than 30 years. It was resolved that the regulations of the "Coats Memorial Scholarship," founded in memory of the late Professor Joseph Coats, should include a condition to the effect that the holder of the scholarship must engage in "research work in pathology during a winter and a a summer session either at the Western Infirmary or in some other laboratory approved by the medical faculty" The Court appointed Dr. D. O. McVail as its representative on the committee of management of the Glasgow Samaritan Hospital; and re-elected Dr. Charles Workman as lecturer and examiner in pathology. A gift to the library of 1080 volumes from Sir W. T. Gairdner, K.C.B., was announced, and also a number of recent surgical works from Dr. J. H. Nicoll. It has been decided that the academic celebration of the ninth jubilee of the University shall be held on June 12th, 13th, and 14th, 1901. In connexion with this event a fund is to be raised to extend the University laboratories. As a contribution to this fund a donation of £5000 from Mr. J. Templeton is announced, and several donations of £1000 have also been promised.

Death of Thomas Wilson Jenkins, M.D., C.M. Glasg.

There are many, both at home and abroad, who will hear with deep regret of the death from phthisis pulmonalis, and at the early age of 38 years, of this able gynæcologist. His kindliness of disposition, his skill and thoroughness in work, and his ready help in consultation, will be greatly missed by his colleagues in the Victoria Infirmary and the Glasgow Samaritan Hospital and by a large professional circle in and round Glasgow. The pathos of his death lies largely in the fact that he has been cut down just as he had begun to reap the fruits of many years' honest work in the shape of a large and increasing consulting practice.

Degrees in Public Health and Science at Glasgow University.

The General Council of Glasgow University has made a representation to the University Court advocating the establishment of degrees in science and public health, on the understanding that laboratory instruction of the kind desiderated by the late Universities Commission was now given in the University. In 1895 the commissioners wrote that they could not have such degrees in Glasgow University till proper laboratory accommodation was provided. The required laboratory accommodation was duly obtained, but then a proposal was made by Professor Sir W. T. Gairdner to have a professorship of public health separate from that of medical jurisprudence, and while this was under consideration the matters came to a standstill. The whole matter has been remitted to a committee of the University Court for information and report.

Medical Appointments and Vacancies.

The following gentlemen having passed the necessary examinations have been elected Fellows of the Faculty of Physicians and Surgeons of Glasgow: Mr. William Donald Anderson, Dr. James G. Connal, Dr. Alexander Macphail, and Dr. John H Teacher.—The positions of obstetric physician and assistant obstetric physician to the Glasgow Maternity Hospital are advertised as being vacant, the term of office of Dr. Malcolm Black and Dr. Munro Kerr respectively having expired.—The University of Glasgow has received from the War Office a communication stating that a number of medical men are required for service in South Africa to replace others whose period of service is about to expire. The engagement is for a year, the pay being £1 a day with free passage and allowances for rations, horse, and service, and two months' full pay on satisfactory completion of the term of service. Applicants must apply personally to the Dean of the Medical Faculty. Dr. Robert Steel has resigned his appointment as assistant dispensary physician to the Glasgow Royal Infirmary.

Aberdeen Hospital Saturday Fund.

Last year's total income of the Aberdeen Hospital Saturday Fund amounted to £1009 10*s.* 7*d.*, and the aggregate expenditure to £281 7*s.* 2*d.*, leaving in the bank the sum of £728 3*s.* 5*d.*

Dec. 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dr. Steevens' Hospital, Dublin.

AT a meeting of the governors and guardians of Dr. Steevens' Hospital, held on Dec 11th, the following appointments were made on the staff: Assistant physician: T. Percy C. Kirkpatrick, M.D. Dub. Pathologist: Francis C. Purser, M.B. Dub.

Royal College of Surgeons in Ireland.

At a meeting of the Fellows, held on Dec. 17th, Sir William Thomson was elected a Member of Council of the Royal College of Surgeons in Ireland.

Coombe Lying-in Hospital, Dublin: Election of Master.

Dr. Frederic Kidd's term as master of the Coombe Lying-in Hospital having expired, the election to the vacant office—tenable for the next seven years—took place on Dec. 16th in the board room of the institution. There was a full attendance of the governors of the hospital, the Lord Mayor filling the chair. The election was by ballot, but as each of the candidates—Dr. Cole-Baker and Mr. Thomas G. Stevens—received an equal number of votes the matter was decided by the Lord Mayor who gave his casting vote in favour of Mr. Stevens. The closely contested election created much interest in medical circles. Mr. Stevens, who is a Fellow of the Royal College of Surgeons in Ireland, was formerly assistant master to the Coombe Hospital.

Will of the late Sir William Stokes.

The personalty of Sir William Stokes of 5, Merrion-square, Dublin, President of the Royal College of Surgeons in Ireland, 1886, surgeon-in-ordinary to the Queen, who died at Pietermaritzburg on August 18th, is entered at Somerset House as £11,646. Letters of administration to the deceased's estate have been granted to his widow.

Catholic University Medical School.

The first annual dinner of the students of the Medical School of the Catholic University was held on Dec. 13th under the presidency of Sir Christopher Nixon, M.D. R U.I. Dr. More Madden proposed in eloquent terms the toast of "The School and its Teaching Staff," which was responded to by the chairman, who mentioned the following interesting facts. In 1880 there were 577 medical students in Dublin; of these Trinity College had 220, the Royal College of Surgeons 243, and the Catholic University 114. In 1900 the total number of students was 401, of which Trinity College held 120, the Royal College of Surgeons 125, and the Catholic University 156.

The Cookstown Guardians and the Appointment of Midwives.

The Local Government Board having urged the guardians of Cookstown, Co. Tyrone, to appoint a midwife for the Stewartstown district they declined, notwithstanding that the medical inspector of the Local Government Board attended their meeting and urged them to do so. The matter came up again at the weekly meeting of the guardians on Dec. 9th, when the chairman moved that steps should be taken to appoint a midwife for Stewartstown, but he was beaten by a majority of 20 votes to 4. The objection made to the appointment was that it meant the cost of £2 for each case, while it would be better for the guardians to employ a medical man to attend such cases and to give him the usual fee of 10*s.* The next step in the matter rests with the Local Government Board.

New Departments in the Royal Hospital, Belfast.

The Board of Management have just given their consent to a suggestion from the medical staff to establish a new special department for dermatology (the work to be done by one of the present staff), and to appoint two anæsthetists, whose duty it will be to administer ether, chloroform, &c. It is felt that the time has come to specialise in the administration of anæsthetics and also to teach students in such important medical duties.

The Ulster Medical Society.

The second meeting of this session was held in the Museum, Belfast, on Dec. 6th, Professor W. H. Thompson, the President, occupying the chair.—Professor J. W. Byers showed an Ovarian Cyst in the interior of which at one place, after removal, some papillomatous growths were detected. There was no sprouting through the cyst wall. The patient made an uninterrupted recovery, but two weeks afterwards a small papillomatous warty growth appeared in the wound. At the time of operation the peritoneum was healthy but vascular. Professor Byers also showed a large Fibroid Tumour enucleated from the right wall of the vagina. The patient, a married woman, aged 27 years, was confined of her third child in January, 1900, and had no difficulty at the birth. In the previous October she had first noticed a swelling in the vulva. A month before admission to the Royal Victoria Hospital (Nov. 12th, 1900) she had suffered from a foul-smelling discharge and the swelling had enlarged. On admission she was in a state of septic intoxication (sapræmia), with high fever and small pulse. Protruding from the vulva was a decomposing tumour which bulged out the right side of the perineum and which had caused a perforation by sloughing immediately outside the greater labium. The tumour was attached by its base to the vaginal wall, from which it was enucleated, and was œdematous and larger than a fœtal head at term. It had no connexion with the cervix or uterus, which were natural in size, but were pushed upwards and to the left by the vaginal mass. The cavity out of which the tumour was shelled was brought together by sutures and gauze-packed. The patient made a good recovery. Professor Byers spoke of the rarity of vaginal fibroids; it was the first he had removed. He referred to A. R. Simpson's, Pozzi's, Breisky's, Lewers's, and Veit's articles on the subject.—Dr. John Campbell showed a Moveable Kidney removed by Lumbar Nephrectomy on account of advanced suppuration (probably tuberculous), a Fibroma of the Ovary (simulating a uterine fibroid on the back of that organ) removed by Vaginal Section, two Uteri removed by Vaginal Hysterectomy for Cancer of the Cervix, an Ovarian Cyst with Myomatous Degeneration, a Papillomatous Ovarian Cyst, and a Fibroid removed by Retroperitoneal Hysterectomy.—An interesting discussion followed, the special points referred to being the presence of malignancy in ovarian tumours, the frequency of moveable kidney, and the rarity of vaginal fibroids.—Dr. W. Calwell showed a Brain from a case of Hæmorrhage into the Pons and gave an account of the case. He also showed the specimens from a patient who had died with deep jaundice. No tumour could be discovered during life, but post mortem the head of the pancreas was invaded by a small malignant growth which completely compressed the bile-ducts.—Dr. V. G. L. Fielden read a paper on the Relative Value of the Various General Anæsthetics, in which he discussed fully the properties of nitrous oxide, chloroform, ether, A.C.E. mixture and methylene, and the use of morphia preceding chloroform.—A long discussion ensued in which Dr. John Campbell, Dr. A. B. Mitchell, Dr. Charles Kevin, Professor T. Sinclair, Dr. A. Fullerton, and Professor Byers took part.

Banbridge Union Hospital.

Mr. James Waddell has been appointed medical officer to the Banbridge Union Infirmary and Fever Hospital in succession to the late Dr. J. Hawthorne.

The late Professor Cuming, M.D. R.U.I.

On Dec. 14th, in the presence of many of the late Professor Cuming's colleagues and medical and personal friends, Mrs. Pirrie unveiled his portrait. Mrs. Pirrie has done much for medical charities in Belfast and was a most intimate friend and patient of Professor Cuming. The memorial portrait, which his admirers had determined to be the most suitable reminiscence of his connexion with Queen's College, Belfast, where he was Professor of Medicine, will remain in the Examination Hall of the College. The President of the College occupied the chair at the unveiling and speeches eulogistic of Professor Cuming were delivered. The portrait, which has been painted by a local artist, is a good likeness; and is to be hung in the Examination Hall in line with other pictures of former professors.

Dispensary Medical Officers' Holidays and Substitutes.

The Ballymoney Guardians have agreed to appoint a committee consisting of two members of each dispensary district to confer with the medical officers and, if possible, come to an arrangement with them, under which they will accept a certain fixed sum per annum, arranging for their own vacations and substitutes. The committee is to report to the board.

Dec. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Phosphaturia in Dyspeptics.

M. ALBERT ROBIN, who is specially interested in the clinical chemistry of urine and also in the treatment of dyspepsia, read a most interesting paper at a recent meeting of the Academy of Medicine. The paper dealt with that class of patients who from time to time pass urine which is milky from the presence of a quantity of phosphate of lime in suspension. Up to now as a rule these patients have been described as prone to calculi, to phosphaturia, or to neurasthenia, whereas in reality they only suffer from atonic dyspepsia, either occasional or chronic, and exhibit in an exaggerated form a phenomenon which exists in a less pronounced form in the majority of atonic dyspeptics. Such patients may be divided into two classes, according as to whether their urine is simply milky or a chalky liquid looking somewhat gritty, the passage of which often gives rise to extremely painful vesico-urethral crises. These patients also present other groups of symptoms generally connected with the nervous, cardiac, cutaneous, or muscular system, the whole forming a very consistent physiological picture which the physician is soon easily able to recognise if he notes the gastric derangement which is generally overlooked but which is nevertheless always present in such cases. If an analysis be made of the contents of the stomach there will be found to be a considerable excess of hydrochloric acid with a slight amount of ferments. Peptonisation is efficiently performed but amylaceous digestion is most insufficient. The metabolism of nitrogenous materials is but slightly modified. These patients are not real phosphaturics, in the sense that the total quantity of phosphoric acid eliminated and calculated as so much per kilogramme of body weight in 24 hours is not as a rule increased, neither is its ratio to the total nitrogen. The form under which the acid is excreted is that of a bicalcic phosphate. It is this salt of lime which, passing out in the urine, makes it milky and a lessened acidity of the urine is one of the conditions which favour the occurrence of this deposit. An important point to notice is that this precipitation of phosphates may take place not only in the bladder but also in the pelvis and tubules of the kidney—a condition which may possibly lead to cystitis, pyelitis, pyelo-nephritis, and hæmaturia, while the irritation caused by the constant passage of the little crystals of calcium phosphate opens the door to sundry infections, as, for instance, that caused by a catheter. In these patients examination often reveals the presence of white corpuscles in the urinary sediment. They commonly suffer from albuminuria and anæmia. The treatment, said M. Robin, should be directed towards relieving the dyspepsia. The patient should be kept for eight days upon a strictly milk diet. Then the phosphaturia may be attacked by the administration during meals of a few drops of a mixture of sulphuric acid, nitric acid, and alcohol. The attacks of pain are best met by prescribing two or three tumblerfuls of some mineral water and the general nutrition should be attended to and tonics, such as iron, arsenic, and the hypophosphites, may be given.

A Coöperative Restaurant for Students.

A coöperative society has just been organised in Paris with a view to open in the Latin Quarter a restaurant for the exclusive use of students. This restaurant will be carried on under special conditions of a nature which will be eminently suitable to the student's purse, which is never too well furnished. The total capital is to be 30,000 francs, divided into 1200 shares of 25 francs each. The sum to be paid on application is one-tenth—i.e., 2·50 francs—being the smallest proportion allowed by the law to be paid on application, so that the poorest student will be able to apply. The remainder of the sum—namely, 22·50 francs—will be paid off by instalments of five centimes at every meal, so that after 450 meals, or in seven and a half months, the student, almost without knowing it, will have fully paid up his holding. The share will carry interest at the rate of 4 per cent., the maximum allowed by law whatever be the profits. The latter will be divided proportionally to the meals taken. This philanthropic notion has been warmly welcomed in university circles and the managing committee teems with the names of the most distinguished graduates. A meeting of shareholders will be held to decide sundry questions, such as whether meals shall be served *à la carte* or *à prix fixe*, whether past students shall participate, and whether students may bring guests, and the like. The provisional committee hopes to open the restaurant in February next. The idea is derived from that of a working men's society at Lille which was opened eight years ago. Commencing with ten members and a capital of ten francs, it now numbers 6000 families and possesses a recreation room, a library, a benefit club, a savings bank, a brewery, a bakery, and other branches. The bakery in 1899 made a profit of 200,000 francs. These results are encouraging for French students.

The Small-pox Epidemic.

The epidemic of small-pox to which I have already referred shows no sign of decreasing. During the past week there have been 17 deaths, which is as high a death rate as any recorded since the beginning of the epidemic. The incidence of the disease is particularly heavy in the *arrondissements* of the north and east. The prefect of police is carrying through vigorous measures for revaccination, and the stations for free revaccination which have been opened at all the hospitals and at most of the *mairies* are thronged all day long.

Dec. 19th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Siege of the Peking Legations.

DR. VELDE, the medical officer to the German Embassy in Peking, has published in the *Deutsche Medicinische Wochenschrift* an account of the siege of the embassies by the Chinese during last June, July, and part of August. His narrative, which is highly interesting from a general as well as from a medical point of view, states that the Europeans besieged in the embassies numbered 1000, of whom 400 were officers and men of the international forces and 200 were women and children. Moreover, about 3000 Chinese Christians had come to the international area for protection. The women and children were all brought to the British Embassy, which was less exposed than the other embassies to the Chinese shells. The food-supply of the besieged Europeans was generally sufficient but very monotonous, consisting principally of horseflesh, rice, and bread, whilst milk and fresh vegetables were altogether wanting. Some eggs were brought into the embassies surreptitiously during the last stage of the siege. On the arrival of the relieving force food for about a fortnight still remained In the Peitang Cathedral, which was also besieged by the Chinese but had no communication whatever with the embassies during these events, the quantity of food remaining when the siege was raised was only 55 lb. of rice for no less than 3000 people Hygienic measures were taken from the beginning with a view to the prevention of an epidemic. To this end the Chinese families were isolated as much as possible from the Europeans, and the surroundings of the water fountains were kept scrupulously clean. Arrangements were also made for the disposal of fæcal matter and rubbish and a place of interment was provided. The health of the besieged was relatively good, but intestinal complaints were prevalent, especially in infants, owing to the want of milk. Five children died from cholerine and there were 15 cases of dysentery with two deaths exclusively among certain sailors whose commanding officer, although repeatedly warned of the risk he was running, allowed his men to drink from a suspected water-fountain in order, as he said, to accustom them to it. There were four cases of enteric fever with one death, and four cases of scarlet fever, also with one death. An international hospital was established in the precincts of the chancery of the British Embassy, containing a room for operations and five wards for patients. Linen and beds were provided by spontaneous gifts of the besieged families; surgical instruments and dressing materials were contributed by the German and British surgeons. The supply of cotton-wool and gauze failed towards the end of the seige, so that peat (Torf) and saw-dust sterilised by steam had to be used as dressings. Dr. Poole, the medical officer to the British Embassy, and Dr. Velde were in charge of the hospital, the other medical men attending the patients in the other embassies. The medical men were assisted by four men respectively from the British, German, Italian, and American army or navy medical corps. An English trained nurse was at the head of the nursing staff, consisting of four English and American nurses, two French nuns, and six other ladies. Dr. Velde speaks in high commendation of the work performed by them. In the hospital six different languages (English, German, French, Italian, Russian, and Japanese) were spoken, and Chinese had to be used in speaking to the servants. The Russian ladies, who all spoke several languages, proved to be very valuable as interpreters. The hospital was opened on June 20th and closed on August 18th. The number of patients was 166, of whom five were already dead when admitted, 17 died from wounds (13 of them within 24 hours), and two died from dysentery, so that the number of deaths was 24. 126 of the patients were wounded, 40 were sick. As to their nationality there were 55 British, 21 Germans, 18 Russians, 17 Americans, 17 French, 17 Italians, 14 Japanese, six Austrians, and one Dutchman. The weapons used by the Chinese were of every description, from the most antiquated to the most modern rifles and artillery. Fortunately they were very inexpert in using them, so that the number of wounded was relatively small. 97 men were wounded by rifle bullets, 18 by artillery fire, 10 by stones, and one by a lance. Of the wounds 33 were in the head, seven in the neck, 13 in the back and thorax, six in the abdomen, 37 in the shoulder and upper extremity, and 41 in the lower extremity. The principle adopted in the treatment of the wounds was to cleanse them and to apply an antiseptic dressing without plugging the wound. The results were very favourable. Apart from two cases of tetanus no complication happened. Nine primary operations were performed with eight deaths, the operations being three tracheotomies, one laryngotomy, one laparotomy, two cases of trephining, and two cases of ligature of large arteries. Ten secondary operations were performed without a death happening. In general the wounds made by rifle bullets were not very severe, but those made by the Mannlicher bullets were attended with laceration of the surrounding parts owing to the fact that the Chinese had not kept the cartridges in closed boxes but had allowed them to become damp. The casing of the bullets therefore became corroded and they produced explosive effects resembling those of the Dum-Dum bullets.

Illegitimate Children.

At a meeting of the Berlin Society for Public Health Dr. Neumann gave an account of an interesting investigation made by him as to the condition of illegitimate children. With the assistance of various associations, public officials, &c., he was enabled to collect full particulars relative to no less than 7229 children born out of wedlock in 1897. He noted whether the child was born in a hospital, an asylum, &c., or in a private house, whether it was subsequently legitimatised by the marriage of the parents, whether the mother took care of it afterwards or whether it was left in charge of other persons or handed over to the district council for orphans, whether it was alive after one year and if not at what age it died. Dr. Neumann has obtained the remarkable result that about 50 per cent. of these children were taken care of during the first year of life either by their mothers or by both parents, and that about 5000 out of 7200 required no assistance from the district councils for orphans. Dr. Neumann then made some recommendations, the principal one being that homes should be established where pregnant women could live during the last months of pregnancy. Unmarried women, after they were discharged from the lying in hospitals, ought to be provided for until they were able to resume their employment. Illegitimate children ought to be attended by specially-appointed medical men and nurses under the control of the municipal authorities, and a special council ought to be formed whose duty would be to look after these children, as has already been done in Leipzig. Owing to the fact that assistance was required for only about 30 per cent. of the illegitimate children the work of the council and the expenses incurred by the municipalities would be less than might be expected.

ROME.

(FROM OUR OWN CORRESPONDENT.)

An Outbreak of Weil's Disease.

SEVERAL cases of this malady, some of them fatal, have lately been seen in the Roman hospitals. In Italy morbus Weilii is known as febrile jaundice. The fever lasts as a rule 8, 10, or 12 days, and besides jaundice is associated with muscular pains and tenderness, occasional diarrhœa, albuminuria, and polyuria. The temperature tends to oscillate, free perspirations accompanying each fall. There is no characteristic rash, but roseolous spots are occasionally present. As the fever comes to an end the other symptoms also subside, but after an apyrexial interval of some days a relapse usually occurs and the whole syndrome is repeated. There may even be a second relapse. Grave cases are indicated by signs of cardiac weakness, subcutaneous hæmorrhages, and diminution of urine with increase of albumin and abundant tube-casts. Nothing has been found which throws light upon the etiology of the complaint or accounts for its infectious character, nor do the pathological appearances satisfactorily explain the jaundice, the biliary passages presenting nothing abnormal.

The Legislation as to Foreign Practitioners.

The Parliamentary Commission, consisting of six deputies, three of whom are medical men, appointed to examine Santini's draft law for the regulation of foreign medical practice in Italy has accepted the Bill as it stands and has rejected an amendment by the Minister for Foreign Affairs, Visconti Venosta, proposing that existing rights be respected. The Bill will next be submitted to the Chamber of Deputies which it is thought will pass it with little or no alteration. Some opposition is expected in the Senate, but that body is not likely to negative a measure which has passed the Representative Chamber unless for strong reasons of a political kind. The agitation against the foreign medical men is thus approaching its climax, and unless the unexpected happens will soon have attained its object, which is the total abolition of foreign practice, and not the ostensible one of securing reciprocity with other countries. The refusal to respect the rights of those already established in practice will have ruinous effects upon the older men and is a very serious matter for all concerned. Many still find it impossible to believe that the Italian Parliament will perpetrate such a cruel injustice as thus suddenly and without warning to deprive a class of men of their means of subsistence in order to gratify the malignant jealousy of the few bigoted agitators who pretend to represent the medical profession here and who, by persistent abuse, unscrupulous misrepresentations, and false accusations, have done their worst to bring the foreign medical man into disrepute with Government and people. But, unfortunately, it seems only too likely that, yielding to cunning appeals to their patriotism and mostly indifferent to the interests of a class of whom they hear nothing but abuse, the legislature will pass the proposed law without making any provision against the cruel hardships which it will certainly occasion.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The International Sanitary Board.

ONE of the principal subjects of discussion at the present time is the difficulty which has arisen at the International Sanitary Board. Two sittings of the International Sanitary Commission or Superior Sanitary Council have already been interrupted by the foreign sanitary representatives leaving—a course which the ambassadors of their respective countries had instructed them to take because the Turkish Government seem to have forgotten the special regulations defining the composition and work of the sanitary board. The management of the Turkish Sanitary Board is in the hands of a council consisting of 21 members, 13 of whom are foreigners representing the following 13 foreign Governments: Great Britain, Germany, France, Austria, Russia, Italy, Greece, Spain, Holland, Belgium, Sweden, Persia, and the United States of America. The 13 foreign members have each the degree of M.D. except the representatives of Belgium and Sweden. Of the eight members who represent the Turkish Government only three are medical men and only two are not Mahomedans. Of the six Mahomedans only one is a medical man. The Turkish representatives who are not Mahomedans must, according to the stipulations, be medical men: they are the inspector-general of the sanitary service and the inspector-adjoint. Both of them have become well known to the sanitary world, having represented the Turkish Government at the various sanitary conferences held in Dresden, Paris, and Venice in order to decide on the measures to be adopted for the repression of cholera and plague. The inspector-adjoint, Dr. Vitalis, died about three weeks ago in Freiburg after an operation, and the Turkish Government thought that the vacancy thus created might be filled by the appointment of a successor who was not a medical man and had never been in the sanitary service, but who had up to that time been an official in the custom-house. The Turkish Government thereby attempted to infringe the regulations relative to the sanitary board, for these regulations provide that the sanitary inspectors as well as all the officials of the sanitary service shall be appointed by the Superior Sanitary Council. This council meets every Tuesday, and at the meeting held on Dec. 4th a memorandum by the 12 sanitary representatives was read, appointing as inspector-adjoint Dr. Duca Bey, who at present holds the position of Turkish sanitary delegate to the Alexandria International Sanitary Council. He has been an official of the sanitary service for the last 27 years and has visited various provinces of the Turkish empire where epidemics happened to be in progress. Among his services in this respect may be mentioned his work during the epidemic of cholera in Syria in 1875, the epidemic of plague in Mesopotamia, and the epidemic of plague in the province of Yemen in 1880; he also superintended the establishment of the lazaretto of Camaran in the Red Sea in 1883. All the members of the Superior Sanitary Council, the senior of whom is Dr. Mordtmann, the German representative, are of opinion that Dr. Duca Bey is the right man for the place, and the ambassadors have already signified their approval of the appointment. The Sultan has still to sanction it, and it remains to be seen whether he will find a way of defeating the intentions of the Superior Sanitary Council supported by the ambassadors, and of maintaining the appointment of the custom-house official to be a member of the sanitary board. It would not be astonishing if he should prove to be successful. The vice-president of the Superior Sanitary Council is a very respectable person, a novelist and a poet, but he is not a medical man; of the other Turkish members one is the chief accountant of the sanitary board, one is the secretary-general, and one is a medical man, as already stated. Their salary is about £T50 per month, the vice-president's being £T80 per month, paid regularly out of the sanitary funds. During the year completed at the end of February, 1900, the revenues of the Turkish sanitary administration were 6,510,920 piastres, representing about £60,000 sterling. Of this sum 50 per cent. was paid by the British, 15 per cent. by the Greeks, and the remainder by the other nationalities.

Persian Hospital in Constantinople.

In THE LANCET of Oct. 27th, p. 1245, I mentioned that the Shah of Persia during his visit to Constantinople granted £T500 to the Persian Hospital which is to be established here and he has also intimated his intention of paying a like amount annually. The hospital will at first have 25 beds, and only poor Persians will be treated gratuitously. Patients belonging to other nationalities will only be admitted on payment. The same practice is followed in the other foreign hospitals here, except in the British Hospital, where British sailors are almost the only patients, British subjects of other occupations being very rarely admitted and women never.

The Pasteur Institute.

In THE LANCET of Sept. 8th, p. 780, I remarked with respect to the Pasteur Institute in Constantinople that the former director, Dr. Zoeros Pasha, had been removed and succeeded by Dr. Mari in consequence of the death of an officer of the Turkish army who had been bitten by a rabid dog but not sent to the Pasteur Institute for treatment until the symptoms of rabies had manifested themselves. Since the removal of Dr. Zoeros Pasha many deaths from rabies have occurred in spite of treatment. A fresh case was reported on Dec. 7th, the patient being an Albanian who received antirabic treatment in the Pasteur Institute, but three days after being discharged he showed symptoms of rabies which eventually proved fatal.

Dec. 14th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in New York City.

SMALL-POX has broken out on a somewhat large scale on the west side of New York city. As a matter of fact there must have been several cases of the disease existing for some little time, but it was not until Thursday, Nov. 29th, that the outbreak was sufficiently alarming to be brought to the notice of the health authorities. On that day upwards of 30 persons, mostly children, were found to be suffering from the disease, and that the contagion will spread further seems certain. The epidemic is believed to have originated from two negro vaudevillists from Pittsburg. The authorities declare that there is no reason for unusual alarm, but the occurrence will tend to impress upon people who may have imagined themselves outside the zone of possible contagion the wisdom of having themselves and their families vaccinated. The vaccinators are now working by night and day in the tenements of the district infected. At present, so far as is known, the malady is confined to one block, most of the tenants of which are negroes, and the victims thus far are mainly children. Dr. Benedict of the Health Board stated as his opinion that further cases must be inevitably looked for in the course of the next few weeks as the exposure had been too great to admit of the hope that all the cases had been already reported. The action of the Health Board in epidemics of a contagious nature is judiciously energetic. When a case of small-pox is discovered every inhabitant of the tenement or dwelling-house is vaccinated, the building is fumigated from top to bottom, and the inspectors visit it once in every 24 hours, keeping up such visits for two or three weeks. There is small room for wonder that small-pox has been brought to this city, as there are many cases in the northern part of the State and in Maryland on the east and south. Communication both by ship and train takes place between these localities and New York every day. It is said that so many cases have not been discovered in one day since an outbreak which occurred about eight years ago. The reason given for the disease gaining so much ground before detection is that the poor population inhabiting the district regard sickness, especially among children, as of little account, and that until it became too grave to be longer neglected parents saw no necessity for calling in a medical man, and thus many were exposed ere medical aid was invoked. It is, however, satisfactory to state that the physicians of the Board of Health declare that there is no cause for needless alarm and express the opinion that the course of the disease will be checked and a widespread epidemic be avoided.

Tainted Water-supply of New York City.

The inhabitants of this city have been seriously alarmed for the past three or four weeks at the condition of the water-supply. The water has had a decidedly unpleasant, oily, fishy taste in addition to being very turbid. Things have come at last to such a pass that an investigation has been demanded and the city has appointed a commission to make an exhaustive inquiry into the whole matter. This commission commenced its session on Nov. 26th, when several witnesses were called upon to give evidence. Among others were Dr. George F. Shrady, editor of the *Medical Record*, and Dr. Charles F. Roberts, chief sanitary inspector of the New York Board of Health. Dr. Shrady was not called as an expert, but rather in the capacity of a private citizen. The proceedings of the commission were *in camerâ*, but we believe that both Dr. Shrady and Dr. Roberts gave it as their opinion that while there was no denying that the water was unpalatable to a degree—in fact, almost nauseous—it was not especially prejudicial to the health of the consumers. Dr. Shrady suggested, and Dr. Roberts recommended as a remedy, that a filtration plant should be constructed. The reason given, and undoubtedly the right one, for the contaminated water is the long-continued drought. It always happens that in May and November the water department has to blow off the hydrants to get rid of the accumulation of organic matter. This year the trouble has been aggravated owing to the scant supply of water in the lakes and reservoirs. This is the season of the year when the fish move. As is well known they always seek deep water, and for months past they have have been compelled to go lower and lower. In moving they stir up the sediment, and the water becomes charged with organic matter. Again, the bottom of the reservoirs and lakes are more or less covered with vegetable growth, and when the water is very low some of the vegetable matter becomes decomposed and communicates its taste to the water. That such is the case has been amply demonstrated within the past few days. On Nov. 24th heavy rain began in New York and the neighbourhood which lasted off and on until almost three inches had fallen. As soon as the water in the reservoirs had risen considerably the supply was much less turbid and somewhat less tainted. The fear has been widespread that the water contained germs of disease and rumours have been current that an outbreak of typhoid fever might be anticipated. Dr. Murphy, president of the Board of Health, ordered the water to be examined by bacteriologists and chemists. Dr. Hermann F. Biggs, pathologist to the Board of Health, said that bacteriological and chemical analyses had not revealed any disease-breeding germs in the water; vegetable organisms were found, but nothing particularly deleterious to health. Illnesses caused by digestive disturbances might result but there would be no likelihood of an epidemic of typhoid fever. Of course this is satisfactory as far as it goes and has reassured the inhabitants of New York, but it is plainly evident that steps should be taken to prevent any tainting of water which is intended for domestic consumption, however harmless. It would appear that if the suggestion of Dr. Shrady and Dr. Roberts that a filtration plant should be established in New York were carried out all fear of danger or unpleasantness from drinking the New York water would be obviated. The expense, it is true, would be large It is estimated that a filtration plant sufficient for Greater New York would cost a sum of about $15,000,000 (£3,000,000), but after all a system which ensured a pure water-supply would be well worth the outlay. By some it is urged that the only effectual remedy would be to get a larger water-supply somewhere. If, however, this were done the water would most probably have to be filtered. The conclusions of the commission after it has received and duly weighed the necessary evidence will be awaited with much interest. It seems certain that radical measures will be taken to procure for New York a pure as well as bountiful water-supply. The Health Board of New York, which is a model of what health boards should be, has in this matter, as in every question affecting the hygiene of the city, exerted itself to the utmost.

Dec. 12th.

Obituary.

JAMES MICHELL WINN, M.D. GLASG., M.R.C.P. LOND.

WE regret to announce the death of this gentleman, one of the fathers of the profession, at his residence, 87, Goldhurst-terrace, Hampstead, on Dec. 8th in his ninety-second year. Dr. Winn was the oldest M.D. of Glasgow University and also the fourth in the list of the Members of the Royal College of Physicians of London, being the eldest in point of age, although there is a senior to him by six months among the Fellows of the College. Dr. Winn was born in the parish of Budock in Cornwall on Dec. 25th, 1808. When about five years of age he went to reside with his parents at Lisbon and was a resident in the Peninsula when the battle of Vittoria was fought in 1813. On returning to England his family resided for several years in London. Dr. Winn was educated at the Stockwell Park Academy. He commenced his medical studies at St. George's Hospital under Sir Benjamin Brodie and Dr. Chambers, who were then on the staff of that hospital On leaving St. George's Hospital he went, in 1832, to the University of Glasgow to study for the M.D. degree. At that time the cholera had made its first appearance in England and the average daily deaths at Glasgow amounted to upwards of 100 This gave Dr. Winn a good opportunity for studying the nature and treatment of that complaint at the Glasgow Cholera Hospital. On returning to England he commenced to practise as a consulting physician and was appointed honorary physician to the Royal Cornwall Infirmary at Truro, a position which he retained for 14 years. In 1852 he came to London, where he made psychology his chief study and contributed numerous articles on that subject to the *Journal of Psychological Medicine*, in which he combated the doctrines of the materialistic school. He also published treatises on "Materialism" and "Collapse of Scientific Atheism." He had written previously to this, in 1848, "A Critical Treatise on the General Paralysis of the Insane," which was very favourably referred to by Dr. Conolly in his Croonian lectures delivered by him before the Royal College of Physicians of London. Dr. Winn's chief work was on the "Nature and Treatment of Hereditary Disease," published in 1869 In this he propounded the theory that all hereditary disease was interchangeable—in other words, mutually convertible. From this generalisation Dr. Winn deduced rules for the regulation of marriages. The late Sir Thomas Watson, in a letter to Dr. Winn, said, referring to this theory of hereditary inter-changeableness in disease: "You appear to me to be probably correct and suggest to me a wide practical application." Dr. Winn's last work was published a few years ago and in this brochure he made his final onslaught on the materialists. Dr. Winn was buried at Kensal-green Cemetery on Dec 12th. He will be remembered as a devoted Christian, kind to those in adversity, and a peacemaker, and his death will be regretted by all who knew him.

CHARLES SEYMOUR STRICKLAND DUNLOP, L.R.C.P. LOND., M.R.C.S. ENG.

IN our list of deaths to-day on page 1852 is the name of Mr. Charles Seymour Strickland Dunlop. We are very sorry to have to record Mr. Dunlop's death. He was the son of Dr. Andrew Dunlop of Jersey who is not only much esteemed in the profession but who had eight sons, all in Her Majesty's service and most of them in Africa. Two of them were in Ladysmith during the long siege. One of them unfortunately died from enteric fever, the other did valuable work as transport officer in Cæsar's Camp. And now we have to notice the death of another son near Lagos. Mr. C. S. S. Dunlop was the eldest son, a member of Dr. Dunlop's own profession, to whom he looked for help at home, for, according to his contract, he should have left West Africa on Sept. 17th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Duplouy, formerly chief of the French Naval Medical Department.—Dr. Deroide, Professor of Pharmacy in Lille.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations at the October Quarterly Examination have been admitted Members of the College and have received their diplomas—viz.:

Harry Cole Alderman, Yorkshire College and Royal Infirmary, Leeds; Percy Francis Alderson, Middlesex Hospital; Arthur Ponsonby Moore Anderson and Arthur de Chair Baker, Cambridge University and London Hospital; Walter Biggar Bannerman, London Hospital; Douglas James Bedford, Cambridge University, St. Thomas's Hospital, and Mason University College, Birmingham; Herbert Arthur Beetham, Yorkshire College and General Infirmary, Leeds; Kenneth Hugh Bennett and Sidney Brée, University College Hospital; Henry Arthur Bramsdon Bransbury, St. George's Hospital; Henry Braund and James Alfred Butler, Guy's Hospital; Richard Henry Botham, King's College Hospital; Allen Bathurst Brown and Charles Richard Verling Brown, St. Bartholomew's Hospital; Frederic Ernest Brunner, Cambridge University and St. Bartholomew's Hospital; Reginald Shirley Burd, Mason University College, Queen's, and General Hospitals, Birmingham; Adrian Caddy, St. George's Hospital; Percy William Leopold Camps, Guy's Hospital; Frederick Charles Carlé, King's College Hospital; Hector Alfred Colwell, St. Bartholomew's Hospital; Herbert Edward Crawley, Oxford University and St. Mary's Hospital; David Morgan Davies, St Mungo's College, Glasgow, and London Hospital; William Stewart Dickie, St. Mungo's College and Royal Infirmary, Glasgow; Robert Dunstan, London Hospital; Arthur Edmunds, King's College Hospital; Frank Payne Edwards, Cambridge University and Westminster Hospital; Gerald Dundas Edwards, Cambridge, Bristol, and St. George's Hospital; Reginald Ambrose Facey, Percy Reginald Fort, and Arthur Herbert Foster, St. Mary's Hospital; George Victor Hamlyn Fairhall, Melbourne University and Westminster Hospital; Louis Patrick Farrell, Dalhousie University and University College Hospital; Edgar Hall Felton and David Forsyth, Guy's Hospital; Benjamin Gregory Fiddian, University College, Cardiff, and Charing Cross Hospital; Welby Earle Fisher, University of Dunedin, New Zealand, and University College Hospital; Cecil Hughes Francis-Williams, St George's Hospital; John Stansfield Gayner, St. Bartholomew's Hospital, Kenneth Weldon Goadby, Guy's Hospital; Lachlan Gollan, University of Melbourne and St. Mungo's College and Royal Infirmary, Glasgow; Ernest Victor Gostling, Cambridge University and St. Thomas's Hospital; John Maxwell Gover, University of Durham; William Henry Clayton Greene, Cambridge University and St. Mary's Hospital; William Wilfrid Halsted, St. Thomas's Hospital; George Hamilton, University of Dunedin, New Zealand, and Middlesex Hospital; Harold Charles Harrison, Firth College, Sheffield, and St. Bartholomew's Hospital Charles Montague Heanley, St. George's Hospital; Charles Edward Hicks and Stanley Hodgson, Guy's Hospital; Cyril Evelyn Hogan, St. Bartholomew's Hospital; Ernest Henry Hogg, Middlesex Hospital; Hugh Hughes, University College and Royal Infirmary, Liverpool; Thomas Hugh James Ellis Hughes, King's College and St. Mary's Hospital; Edmund Henderson Hunt, Oxford University and St. Bartholomew's Hospital; Bertram Fowler Hussey, St. Mary's Hospital; Robert Jaques, University College, Liverpool, and King's College Hospital; Edward Angas Johnson, Adelaide and Melbourne Universities, St. Bartholomew's and London Hospitals; Duncan Matheson Johnston, Durham University and St. Bartholomew's Hospital; Ernest William Julius Ladell, Edward Vaughan Lindsey, John Allden Lloyd, and Francis Henry Lowe, St. Bartholomew's Hospital; Peter N. Lakshmanan, University of Madras and King's College Hospital; Brinley Richard Lloyd, University College, Cardiff, and Charing Cross Hospital; Richard Ernest Lloyd, University College Hospital; Ernest John Manning, St. Mary's Hospital; James Cole Marshall, and Samuel Mason, St. Bartholomew's Hospital; Talbot Carter Mitchell, Yorkshire College and General Infirmary, Leeds; Harry Tudor Newling, Royal Infirmary, Durham, and St Mary's Hospital; William Walker Maxwell, Edinburgh University and King's College Hospital; John Campin Newman, Cambridge University and St. Bartholomew's Hospital; John Chalmers Norton, University College and General Infirmary, Bristol; James Christopher Oates, Mason College, Queen's and General Hospitals, Birmingham; William Sidney Page, St. Mary's Hospital; Hugh McDowall Parrott, Guy's Hospital; Eustace Murray Bruce Payne, St. Bartholomew's Hospital; John Shirley Steele Perkins, Cambridge University and Guy's Hospital; Philip Meyler Perkins, Durham University and St. Bartholomew's Hospital; Miles Harris Phillips, University College and Royal Infirmary, Bristol; Lionel James Picton, Oxford University and St. Bartholomew's Hospital; Georges Woodyatt Prodter, Durham University and Middlesex Hospital; John Percy Race, Owens College and Royal Infirmary, Manchester; John Evans Richards, Charing Cross Hospital; Bernard Hamilton St. Clair Roberts, Mason College, Queen's and General Hospitals, Birmingham; Reginald Percy Richardson, Durham University and Westminster Hospital; Alfred Reginald Roche, Cambridge University and Westminster Hospital; Edward Norman Tilly Rogers, Middlesex Hospital; Frederick Colin Rogers, St. Mary's Hospital; William Edward Ruttledge and Thomas Copeland Savage, University College Hospital; Henry Scanlan, McGill College, Montreal, and St. Bartholomew's Hospital; Robert Westley Shaw, Western University, Ontario, and University College; Francis Wheler Sime, Durham University and Guy's Hospital; Fred Algernon Simpson, Cambridge University, St. Mary's and St. George's Hospitals; Frank Blenkinsopp Skerrett, Owens College and Royal Infirmary, Manchester, and St. Thomas's Hospital; Robert William Innes Smith, Edinburgh University and King's College Hospital; Charles Duncan Soutter, Mason University College, Queen's and General Hospital, Birmingham: Harold Robert Dacre Spitta, St George's Hospital and Durham University; Louis Edward Stamm, Guy's Hospital; Charles Mon Stewart, University of Toronto and University College Hospital; Fred Stuart, University of Durham and St. George's Hospital; Walter James Susmann, Cambridge University and St. George's Hospital; John Tattersall, St. Mary's Hospital; Arthur James Tayler, King's College Hospital; Evelyn Davison Telford, Cambridge University, Owens College, and Royal Infirmary, Manchester; William Murray Thomas, Guy's Hospital; George William Thompson, Edinburgh University; Robert Cyril Turnbull, London Hospital; Alexander Robert Tweedie, St. Bartholomew's Hospital; Geoffrey Allen Upcott-Gill, University College Hospital; Charles Ernest West, Oxford University and St. Bartholomew's Hospital; Charles Vaughan White, St. Thomas's Hospital; Clare Aveling Wiggins, St. Mary's Hospital; Archibald Robert Barclay Williamson, Queen's University, Kingston, Canada; and Thomas James White, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—At the examinations for Medical and Surgical Degrees, Michaelmas Term, the following candidates were successful:—

FIRST EXAMINATION.

Part I.

Chemistry and Physics—A. G. Atkinson, Trinity; G. F. S. Bailey, Caius; J. H. Board, Pembroke; S. Churchill, Trinity; E. B. Clayton and A. I. Cooke, Caius; W. D. Coplestone, Jesus; H. B. Corry, Caius; G. H. Drew, Christ's; H. B. Ellison, Caius; D. Embleton and H. J. Tardon, B A., Christ's; H. J. Gauvain and S. Gooding, St. John's; J. W. Grice and F. W. W. Griffin, King's; M. Grundy, St. John's; T. S. Hele, Emmanuel; A. L. Hetherington, Trinity; V. C. Honeybourne, St. John's; N. G. Horner, Caius; C. E. M. Jones, King's; P. P. Laidlaw, St. John's; K. A. Lees, King's; L. F. G. Lewis, Christ's; C. Lillingston, Pembroke; J. W. Linnell, St. John's; P. C Litchfield, Trinity Hall; R. B. Lloyd, Emmanuel; S. G. Luker, Pembroke; S. G. MacDonald, St. John's; L. H. L. MacKenzie, Trinity; H. W. Moxon, St. John's; H. F. G. Noyes, Caius; G. G. Packe, Trinity; H. A. Pontifex, Pembroke; J. M. Postlethwaite, Emmanuel; R. L Rawlinson, Trinity; E. Sandbach, King's; W. H. Simpson, Caius; J. M. Smith, Christ's; A. H. C. Suhr, Caius; W. H. R Sutton, Downing; R. Svensson, Caius; H. H. Taylor, Pembroke; C. B. Ticehurst, St. John's; R. Wade, Christ's; S. L. Walker, Sidney Sussex; G. H. H. Waylen, King's; H. P. Weaver, B A., Trinity; and O. K. Wright and R. F. Young, Christ's.

Part II.

Elementary Biology.—A G. Atkinson, Trinity; G. F. S Bailey, Caius; G. B. Bartlett, Sidney Sussex; R. L. Barwick, B.A., Christ's; A. E. Bonny, Sidney Sussex; H. A. Browning, St. John's; R. Burgess, Caius; A. F. Burton, Christ's; C. St A. Coles, Trinity; W. D. Coplestone, Jesus; G. W. Craig, Emmanuel; W. F. Denning, Trinity; G. H. Drew and D. Embleton, Christ's; H. J. Gauvain, St. John's; J. L. Graham-Jones, Emmanuel; F. W. W. Griffin, King's; M. Grundy, St. John's; W. H. Hodgson, Christ's; C. J. R. Hoffmeister, Caius; V. C. Honeybourne, St. John's; N. G. Horner, Caius; P. P. Laidlaw, St. John's; K. A. Lees, King's; R. B. Lloyd, Emmanuel; L. H. L. Mackenzie, Trinity; R. M. Miller, B.A., Clare; H. W. Moxon, St. John's; E. V. Oulton, Christ's; H. A Pontifex, Pembroke; R. L Rawlinson, Trinity; E. Sandbach, King's; E F. Skinner, Corpus Christie; J. M. Smith, Christ's; B. S. Taylor, M.A., Clare; C. B Ticehurst, St. John's; C. H. Treadgold, Clare; J. A. Venning, Trinity; B. Wahby, Non-Collegiate; S. L Walker, Sidney Sussex; D. R. P.

Walther, Pembroke; E. G. Wheat, Christ's; and A. E. Wilson-Hird, Clare.

SECOND EXAMINATION.

Part I.

Pharmaceutical Chemistry.—E. E. Atkin, Caius; J. B. Banister, Jesus; S. Barradell-Smith, St. John's; E. Beaton, Caius; E. M. Brown, B.A., Pembroke; J. W. Chell, St. John's; H. M. Clarke B.A., and H. P. Crampton, B.A., Clare; F. D. Crew, B.A., Emmanuel; H. M. Davies, B.A., and C. E. Droop, B.A., Trinity; T. W. Dunn, Caius; R. G. Elwell, B.A., Trinity; A. H. Fardon, Christ's; J. N.-F. Fergusson, St. John's; R. L. Gamlen, Caius; H. P. B. Gough, Sidney Sussex; W. B. Grandage, Clare; J. R. C. Greenlees, St. John's; J. M. P. Grell, H. Selwyn; C. R. F. Hall, B.A., Trinity; H. S. Hall, Pembroke; A. W. Hayward, St. John's; R. A. P. Hill, Caius; W. R. Honeyburne, B.A., Peterhouse; B. L. Hopper, B.A., Caius; C. W. Hutt, Trinity; J. B. Irving, B.A., and G. S. Keat, St. John's; W. Micklethwaite, M.A., Trinity; F. E. Murray, B.A., St. John's; H. Spurrier, B.A., Caius; J. Stirling-Hamilton, B.A., Jesus; A. H. Style, B.A., Emmanuel; H. E. Symes-Thompson, M.A., Christ's; A. E. Taylor, B.A., Downing; N. F. Ticehurst, M.A., Clare; B. L. Thurlow, B.A., Caius; E. G. Wales, B.A., Downing; and F. K. Weaver, B.A., and H. H. Weir, Trinity.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* The Hungarian Ministry of Education has decided to build an Institute of General and Experimental Pathology and Therapeutics; the chair of Children's Diseases, which has hitherto been filled by an extraordinary or assistant professor only, is to be raised to the rank of an "ordinary" professoriate.—*Chicago Medical College:* Dr. John B. Murphy has been appointed to the chair of Surgery.—*Dorpat:* Dr. Raehlmann has resigned the chair of Ophthalmology and Dr. Jewicki of Moscow has been appointed in his place.—*Gratz:* Dr. Meinhard Pfaundler has been recognised as *privat-docent* of Children's Diseases.—*Groningen:* Dr. Wenckebach of Utrecht has been appointed Professor of Clinical Medicine.—*Kiel:* Dr. Ernst Siemerling of Tübingen has been appointed to the chair of Psychiatry.—*Lemberg:* Dr. Victor Wehr, *privat-docent* of Surgery, has been promoted to an Extraordinary Professorship.—*Paris:* Dr. Brissaud, Professor of the History of Medicine, has been appointed to the chair of Medical Pathology.—*Strasburg:* Dr. Goltz, Professor of Physiology and Director of the Physiological Institute, is about to retire at the close of the current session; Professor Fehling of Halle has been elected Professor of Gynæcology in succession to Dr. Freund.—*Tours:* Dr. Delagenière has been appointed Professor of Clinical Surgery and Dr. L. Thomas Professor of Surgical Pathology and Operative Medicine.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Fellows of the College held on Dec. 17th Sir William Thomson was unanimously elected a Member of the Council.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—At the meeting of the Cardiff Town Council held on Dec. 10th the recommendation of the sub-committee that five acres of land in Cathay's Park should be granted for the purposes of erecting new buildings for the University College of South Wales and Monmouthshire was agreed to.

BRISTOL NATURALISTS' SOCIETY.—At a meeting of this society, held at University College, Bristol, on Dec. 8th Mr. W. T. Crank read a paper on The Discovery of a Pre-historic Burial-place at Harlyn Bay, Padstow, Cornwall. Mr. Crank stated that the burial-place, which was accidentally discovered last August, was considered by experts to date from B.C. 500, and he added that Dr. John Beddoe had measured the skulls and bones which had been found and was preparing a report upon them.

HOUSING THE POOR AT SALFORD.—After repeated and much-delayed discussion on the question, the Salford Board has resolved to erect cottage homes at Kenyon Junction, near Culcheth, to accommodate 300 persons, at an outlay of £61,211.

WATER-SUPPLY OF TENBY.—At the meeting of the Tenby Town Council held on Dec. 14th the report of the Water Committee recommending the adoption of a scheme for the filtration of the Ritec water was adopted. The estimated cost was £13 500

BRIXHAM HOSPITAL, DEVON.—At the annual meeting of the supporters of this institution held on Dec. 12th it was reported that during the past year 70 in-patients had been admitted and 885 patients had been attended at their homes (necessitating 10,972 visits). The expenditure was £573, being £13 in excess of the income. Through the generosity of two ladies a new surgery and waiting-room had been added to the hospital.

IN MEMORIAM.—The widow of Mr. Henry Lee, F.R.C.S. Eng., senior consulting surgeon to St. George's Hospital, London, has presented a marble bust of her late husband to the Royal College of Surgeons of England. He was Professor of Surgery and Pathology at the College.—A beautiful bronze relief portrait panel in memory of the late Samuel Gourley, M.D. Glasg., F.R.C.S. Edin., J.P., has recently been put upon one of the walls of the Hartlepools Hospital, where he was for 25 years honorary surgeon.

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.—A meeting in connexion with the Gloucestershire, Somerset and Wilts branch of this society was held at Chippenham on Dec. 7th under the presidency of Sir John Dickson-Poynder, M.P. An interesting address on the "Nature and Prevention of Consumption" was given by Dr. Lionel A. Weatherly. An appeal is being made for funds for the proposed sanatorium, which is estimated to cost £16,000. Several donations have been announced by the honorary secretary, Mr. A. Murray Gray, L.R.C.P. Edin.

BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION: THE CASE OF DR. HENRY WARD IRVINE.—At a meeting of the representative committee of consultants and specialists held at Birmingham on Dec. 3rd the following resolution was adopted:—

> That this meeting of the representative committee of consultants and specialists of the City of Birmingham desires to congratulate the Medical Defence Union and its able and energetic secretary, Dr. A. G. Bateman, upon the successful result of the prosecution of Dr. Ward Irvine before the General Medical Council, and returns very sincere thanks for the assistance afforded to the medical profession in Birmingham.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—A meeting of the Rahere Lodge was held at Frascati's Restaurant, Oxford-street, W., on Tuesday, Dec. 11th, W. Bro. Walter Gripper, M.B. Cantab., the W.M., being in the chair. Bro. R. H. Wellington was admitted to the second degree and Mr. Alfred Hepburn, M.R.C.S. Eng., L.S.A., Mr. Arthur Maitland Ware, M.A., M.B., B.C. Cantab., and Mr. Thomas Jessopp Bokenham, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., were initiated into Freemasonry. W. Bro. D'Arcy Sugden, M.R.C.S. Eng., L.R.C.P. Lond., P.M., the Tyrian Lodge, Queensland, was also elected as a joining member. The brethren and a considerable number of guests, who included the W.M. and S.W. of the Sancta Maria Lodge, subsequently dined together.

CARDIFF INFIRMARY.—At a meeting of the executive committee of the Cardiff Infirmary held on Dec. 12th it was stated that the adverse balance of the institution at present amounted to £11,686. £4737 had been received in response to the effort which was made to clear the infirmary from debt; this sum included a conditional promise of £500.—At a special meeting of the governors of the Cardiff Infirmary held on Dec. 14th the new rule which provided that workmen, members of any trade society, club, &c., or the members of any church association, subscribing to the funds of the infirmary shall be entitled to nominate one person out of the members so subscribing as a president, vice-president, or governor, annually or for life, in the same way as ordinary subscribers, was unanimously passed. This new rule has given great satisfaction to the working classes of Cardiff and one of their representatives stated that had working men been recognised in the past their subscriptions to the infirmary would have been doubled.

ARSENIC IN BEER.—The commission of experts appointed by the Manchester Brewers' Central Association have issued their report, in which they confirm what has already been stated—viz , that the arsenic found in deleterious quantities in the beer has been solely due to the contamination by arsenic of the sugars supplied by a Liverpool firm. The arsenic, they add, was undoubtedly derived from the impure sulphuric acid used in the manufacture of these sugars. We may remark that it has since been stated by the analyst of the city of Manchester that he has found arsenic also in similar quantity in malt and in beer known to be brewed from malt and hops only. In another column we report the presence of arsenic in remarkable quantity in superphosphate of lime which is used largely for fertilising purposes. Possibly this may throw some light on the discovery of the analyst of the city of Manchester.

Parliamentary Intelligence.

HOUSE OF LORDS.

FRIDAY, DEC. 14TH.

Sick and Wounded Colonial Soldiers.

LORD BURGHCLERE addressed a question to the Under Secretary of State for War with reference to the medical inspection and treatment of sick and wounded colonial soldiers sent home from South Africa.—Lord **RAGLAN** explained that wherever it was possible these men were sent direct from South Africa to their colonial homes, but in some cases they had been brought to this country, where at Shorncliffe a depôt for them had been formed. He had visited this depôt. A large number of the men were convalescent and were considered well enough to undertake the long voyage to this country and the greater part of them arrived, he was glad to say, in a state of advanced convalescence. In certain cases the men were not medically examined before they went on board the ship. That was an unfortunate circumstance which the War Office very much regretted and in future arrangements would be made to remedy the mistake He assured the House that the men were provided with superior third-class accommodation, two only being in a cabin, and that they had a suitable dietary.—Earl **CARRINGTON**, who had intended to propose a motion on the subject, refrained from doing so, and expressed satisfaction with the manner in which his representations had been received by the War Office.

HOUSE OF COMMONS.

THURSDAY, DEC. 13TH.

Lead Poisoning in the Potteries.

Sir **CHARLES DILKE** asked the Home Secretary if he could state when the Home Office proposals with regard to lead poisoning in the manufacture of china and earthenware which were contained in a circular to manufacturers issued on Dec 14th, 1899, and again submitted to them as proposed special rules in August, 1900, were to be formally issued as special rules.—Mr. **RITCHIE** replied: Much progress has been made towards a settlement of the special rules for the china and earthenware trade, but there are certain points still outstanding and one of them involves a chemical question on which I am now waiting for a report from Dr. Thorpe, principal chemist to the Government. hope to be able formally to issue the new rules early next year.

The Case of Dr. H. P. Veale.

General **LAURIE** asked the Secretary of State for War, whether Dr. H. P Veale, M.B. Cambridge, and the Rev. J. Godfrey, stated to be a clergyman of the Church of England at Pretoria, whose conduct in regard to the treatment of the British prisoners at Pretoria was reported on by Field-Marshal Lord Roberts in his despatch of June 27th last, were respectively British subjects; and, if so, whether their position in the Transvaal was consistent with their nationality; and if any notice could be taken of their behaviour.—Mr. **BRODRICK**: We are not aware whether Dr. Veale and the Rev. J. Godfrey were British subjects at the time when they were concerned with the treatment of the British prisoners at Pretoria. I am advised that Mr. Godfrey is in colonial orders and that we can take no notice of his behaviour. The question of Dr. Veale's position as a member of the Red Cross Society is under consideration.

Poison in Beer.

Colonel **KENYON-SLANEY** asked the Home Secretary whether the official analysts to the department, Dr. Stevenson and Dr. Luff, who were members of the expert committee appointed by the Manchester Brewers' Association, were acting on behalf of the department, or were being remunerated by the Brewers' Association; and if the latter was the case, whether, in view of the great public interests involved, he would consider the advisability of causing a report to be made by some expert analysts entirely unconnected with the trades concerned.—Mr. **RITCHIE** replied: Dr. Stevenson and Dr. Luff are not acting on behalf of the Home Department. I think that the suggestion in the last paragraph of the question is scarcely within my jurisdiction; but I have consulted the President of the Local Government Board and understand that that department has the whole matter under their active consideration.—Mr. **FREDERICK WILSON** asked the Secretary to the Treasury whether, seeing that it was stated in the report of the Committee on Beer Materials, 1899, that the Treasury was empowered to prohibit the use in the manufacture of beer of any substance or liquor of a noxious or detrimental nature, he would state upon how many occasions within the last five years had the Treasury exercised such power, and how many specimens of cheap sulphuric acid such as was apparently used in the manufacture of sugar for brewing purposes had been examined during the current year.—Mr. **AUSTEN CHAMBERLAIN** replied: The power referred to was conferred on the Treasury by Section 5 of the Customs and Inland Revenue Act, 1888, but the duty of providing proper securities for the wholesomeness of beer, like other articles of food, is placed by law on the local authorities, subject if necessary to the Local Government Board or Board of Agriculture. The Treasury therefore has not exercised this power. Sulphuric acid would only come under the cognisance of the Government laboratory in the event of samples being submitted for analysis under a magistrate's order, and no instances of such submission have occurred. It ought not to exist in any sugar found in a brewery.

Preservatives and Colouring Matters in Food.

Mr. **CHANNING** asked the President of the Local Government Board if he could state when the departmental committee appointed to consider the use of preservatives and colouring matter in articles of food was likely to present its report.—Mr. **WALTER LONG** replied: I am informed that it is not expected that the report will be ready till March next. The committee have deemed it desirable to institute inquiries as to dairies in Denmark and Ireland and they are deferring their report until they have before them the result of these inquiries and of certain physiological experiments which they have directed to be made.

The Constituents of Butter.

Sir **MARK STEWART** asked the President of the Board of Agriculture if it was the intention of the Government next session to appoint a departmental committee to inquire and report as to what regulations, if any, might with advantage be made by the Board of Agriculture under Section 4 of the Sale of Food and Drugs Act, 1899, for determining what deficiency in any of the usual constituents of genuine butter or what addition of extraneous matter should, for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, raise a presumption until the contrary was proved that the butter was not genuine.—Mr. **HANBURY** replied: I will not lose sight of the matter to which my hon. friend refers, but neither my predecessor nor I have yet taken any steps with respect to the setting up of presumptive standards for butter, because it has been thought better to wait and see whether any action can in the first place be taken in the case of milk and cream. The report of the committee appointed to consider the course to be taken with regard to the last-named articles has not yet been received.

FRIDAY, DEC. 14TH.

Inoculation against Enteric Fever.

Mr. **POWELL WILLIAMS**, in reply to a request for information as to the results of inoculation against enteric fever in South Africa, said that statistics are not yet available.

Typhus Fever in the West Highlands.

Mr. **JOHN DEWAR** asked the Lord Advocate whether the Local Government Board for Scotland was aware of an epidemic of typhus fever involving 20 cases (of which six were fatal) between Oct. 1st, 1899, and Feb. 12th, 1900, in the locality between Finsbay and Scadabay in the parish of Harris, in Inverness-shire, having a congested crofter and cottar population of about 1000; and whether the Local Government Board, the county medical officer, and the district medical officer of health failed to visit the locality or to take any steps to check or to assist in checking that epidemic; and whether a public inquiry would be made into the circumstances attending that outbreak.—The **LORD ADVOCATE** replied: The figures given by the hon. Member are, I believe, correct, but the Local Government Board had no special intimation of the outbreak, the existence of which they learned from the regular reports of the medical and sanitary officers. The county medical officer did not visit the locality between the dates specified, but he was in constant communication with the district medical officer who did, and who reported as follows: "The local authority acted very promptly and gave every assistance." On the whole I am satisfied that no more could have been done in the absence of an isolation hospital and I do not see any reason for ordering a public inquiry.

Poison in Beer.

Mr. **WARNER** asked the President of the Local Government Board if he intended to take some further action to stop the sale of poisonous beer, as fresh cases of poisoning were still being reported.—Mr. **WALTER LONG** replied: The Local Government Board have no power to stop the sale of any particular beer, but I may state that there is reason for believing that the cases of illness which are now coming under observation for the first time are in the main those of persons who received the poison some time since.—Mr. **CHAPLIN** asked the President of the Local Government Board if he could state what steps had been taken to ascertain the facts with regard to the alleged poisoning by beer, into which an inquiry had been instituted by the Local Government Board; if he had yet received any information as to the number of persons who had been affected and the number of deaths which were alleged to have been caused by it; and, if not, whether he would make public the information obtained by the Local Government Board as early as might be after he received it.—Mr. **LONG** replied: As this matter has excited considerable public interest perhaps I may be allowed to state somewhat fully the course which has been adopted with respect to it. As regards the steps which have been taken by the Local Government Board I would repeat what was stated by my right hon. friend the First Lord of the Treasury on Tuesday last—viz., that from the first outbreak of the epidemic the Board have had the matter under observation. Dr. G. S. Buchanan, one of the most experienced of their medical inspectors, is visiting the places affected and has been instructed to obtain all possible information on the subject, including the action taken by those interested in the breweries and manufactories of brewers' sugar concerned and by the local authorities for detecting arsenic in beer or other substances which contain chemically manufactured sugar. Moreover, an expert committee, consisting of Sir Lauder Brunton and Dr. Stevenson and Dr. Luff, (the analysts to the Home Office), Mr. Gordon Salamon, Dr. Buckley, and the hon. gentlemen the member for the Launceston Division (Mr. Fletcher-Moulton) have made a careful investigation on behalf of the Manchester Brewers' Central Association. The brewers and manufacturers have given them every possible access to their premises and facilitated in every way their inspection and investigation. The Board's inspector has been in communication with members of the committee and cordial coöperation and assistance have been rendered both to the committee and the inspector by the medical officers of health of Manchester and Salford The House may rest assured that everything practicable is being done to ascertain the facts. I am informed that the association has pledged itself to recall or to destroy all beer in the brewing of which the implicated substances have been used, and that instructions to this effect have been sent to all the brewers of the association The obtaining of information as to the number of persons who have been affected and the number of deaths alleged to have been caused forms part of Dr. Buchanan's inquiry which is not yet complete. His report will be made public as early as practicable after its receipt. I may add that the Board have issued a circular to local authorities recommending them to cause samples to be analysed both of beer and of articles of food in which chemically manufactured sugars may enter.

Proposed Exemption of Hospitals from Rates.

Mr HORNER asked the First Lord of the Treasury whether, in view of the circumstances under which hospitals and institutions of a like kind had to raise funds necessary to carry on their charitable work, it was the intention of Her Majesty's Government to initiate legislation to give effect to the report of the Select Committee of the House of Commons, dated July 13th, 1900, by which it was recommended that the principle of exemption from rates should be applied to hospitals and kindred institutions not carried on for profit or gain and supported wholly or in part by voluntary contributions or endowments, and whether Her Majesty's Government proposed in any way to give effect to the other recommendations of that report.—Mr. WALTER LONG replied to the question, saying: The matter to which the hon Member refers is one of considerable difficulty and forms part of the subject now under consideration by the Royal Commission on Local Taxation. I cannot at present give any promise of its being dealt with by the Government.

SATURDAY, DEC. 15TH.

Close of the Session.

The business of the session was brought to a close to-day, and Parliament was prorogued by commissioners representing Her Majesty. Unless something unexpected happens the new session will not commence before Feb 14th, 1901.

Powell, M.D., sixth edition (H. Kimpton, High Holborn, London), price 7s 6d. net.—Received from Messrs. Bemrose and Sons, 23, Old Bailey, London, Five Calendars for 1901, published at 1s. each.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARBUCKLE, H. W., M D Aberd, D.P.H. Camb., has been re-appointed Medical Officer of Health by the Thorne District Council.

BARCLAY, W. J, M B, B S Edin, has been appointed Assistant Medical Officer for the Dundee Infirmary.

BODMAN, C. OSMOND, M.B, B Sc. Durh, M.R C.S, L R.C.P. Lond., has been appointed Resident Medical Officer to the Royal Hospital for Children and Women, Waterloo-bridge-road, London.

BROGDEN, G. A., M.B, Ch.B Edin., has been appointed House Physician to the Salisbury Infirmary.

BULLEID, ARTHUR, L.R.C.P., L.R C.S Edin, L.F.P.S Glasg., has been appointed Medical Officer of Health for Midsomer Norton, Somerset, vice Alexander Hastings Whicher, resigned.

CLARK, MR., of Truro, has been appointed Public Analyst by the Truro Corporation.

CLAY, D L, L.R.C.P. Lond., M R C.S., has been appointed Surgeon to the Royal mail steamer *Gothic*

CRAWFORD, A. D, M.B, C M. Glasg., has been re-appointed Medical Officer for the Maxstoke Sanitary District, Meriden Union.

DARLEY, A. R., M.D. Dubl. L.M. R.C P. Irel., has been re-appointed Medical Officer by the Daventry Rural District Council.

DIXON, J., M.D. St. And, L.R.C.P. Lond, M R.C.S, has been appointed, *pro tem*, Medical Officer for Rotherhithe.

EDRIDGE-GREEN, F. W, M.D, F.R.C.S, has been appointed Honorary Secretary for England of the International Psychical Institute

FLACK, FREDERICK HENRY, M.B, Ch.B Vict. Univ., has been appointed Junior House Surgeon to the Blackburn and East Lancashire Infirmary.

GOSTLING, E VICTOR, M R.C.S., L.R.C P, has been appointed House Physician to the Derbyshire Royal Infirmary.

HARRISON, EDWARD, M A., M.D. Cantab., F.R.C S Eng., has been appointed Honorary Surgeon to the Hull Royal Infirmary.

KILVERT, J. ELLIS, M R.C S, L.R.C P., has been appointed House Surgeon to the Derbyshire Royal Infirmary.

MACKENZIE, W. L., M D. Aberd., D P.H, has been appointed Medical Inspector to the Local Government Board for Scotland.

McLaws, J., M.B., M.Ch. Glasg., has been appointed Civil Surgeon to the Forces in South Africa.

Manley, J. H. H., M.B., B.C., M.R.C.S., D.P.H., has been re-appointed Medical Officer by the West Bromwich Town Council.

Montgomery, W. P., M.A. Oxon., M.B., B.S. Lond., F.R.C.S., has been appointed Assistant Surgeon to the Manchester Children's Hospital, Pendlebury.

Newman, G., M.D. Edin., D.P.H. Camb., has been appointed Medical Officer of Health by the Finsbury Borough Council.

Park, W., M.B., M.S. Glasg., has been appointed Civil Surgeon to the Forces in South Africa.

Pozzi, Joseph, M.B., Ch.B. Aberd., has been appointed Deputy Medical Officer for the Nelson and Brierfield Sanitary District of the Burnley Union.

Reidy, W. A., L.R.C.P., L.R.C.S., L.F.P.S. Glasg., has been appointed District Medical Officer and Public Vaccinator by the Newport, Mon., Board of Guardians.

Rice, George, M.D. Durh., has been appointed Honorary Physician to the Derbyshire Royal Infirmary, vice C. A. Greaves, resigned.

Shaw, John C., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Royal Ear Hospital, Frith-street, Soho-square, London.

Shera, J. E. P., L.R.C.P., L.R.C.S. Irel., has been appointed Second Assistant Medical Officer to the Kent County Asylum, Chartham, near Canterbury.

Southern, J. Acton, M.R.C.S., L.R.C.P., has been appointed Honorary Surgeon to the Derbyshire Royal Infirmary, vice W. Grafton Curgenven, resigned.

Tennent, J. T., M.B., C.M. Glasg., has been appointed Civil Surgeon to the Forces in South Africa.

Thomas, J. Lynn, F.R.C.S. Eng., has been appointed Surgeon to the Cardiff Infirmary.

Warrington, W. B., M.D. Lond., M.R.C.P., has been appointed Honorary Assistant Physician to the Stanley Hospital, Liverpool.

Williams, W. R. E., M.B., Ch.B. Edin., has been appointed Civil Surgeon to the Forces in South Africa.

Workman, C., M.D., M.Ch. Irel., F.F.P.S. Glasg., has been appointed Lecturer Examiner in Pathology, University of Glasgow.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ancoats Hospital, Manchester.—Resident House Physician for in-patients. Salary £80, with board, &c.

Brighton, Hove, and Preston Dispensary.—Three House Surgeons, one for each Branch. Salary £160 per annum, with furnished apartments, coals, gas, washing, and attendance. Apply to Assistant Secretary, 113, Queen's-road, Brighton.

Burgh of Leith.—Medical Officer of Health. Salary £400 a year. Apply to the Town Clerk, Town Clerk's Office, Leith.

Burgh of Partick.—Medical Officer. Salary proposed £150. Apply to the Clerk to Commissioners, Burgh Chambers, Partick, Glasgow.

Chelsea, Brompton, and Belgrave Dispensary, 41, Sloane-square, Chelsea.—Surgeon.

Cheltenham General Hospital.—Junior House Surgeon for two years, unmarried. Salary £45 per annum, with board, lodging, and washing.

Chester General Infirmary.—Second Resident Medical Officer for six months. Salary at the rate of £80 per annum, with residence and maintenance in the house.

City of London Hospital for Diseases of the Chest, Victoria-park, E.—House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

County Asylum, Whittingham, Lancashire.—Junior Assistant Medical Officer. Salary commencing at £150, increasing to £200, and on promotion to £250, furnished apartments, board, washing, and attendance provided.

Derbyshire Royal Infirmary, Derby.—Honorary Physician.

Doncaster General Infirmary and Dispensary.—Assistant House Surgeon. Salary £50 per annum, with board and residence.

East London Hospital for Children and Dispensary for Women, Glamis-road, Shadwell, E.—Pathologist and Registrar for one year.

Fisherton House Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.—Apply to Dr. Finch, Salisbury,

General Infirmary at Gloucester and the Gloucestershire Eye Institution, Gloucester.—Assistant House Surgeon for six months. Salary at the rate of £30 per annum, with board, residence, and washing.

Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, increasing by £10 a year to £120, conditionally, with board, residence, attendance, and washing.

Hospital for Women, Soho-square, London, W.—Assistant Physician. Also Assistant Surgeon.

Hull Royal Infirmary.—Honorary Assistant Surgeon to Out-patient Department for five years. Also Junior Assistant House Surgeon for one year. Salary £40, with board and lodging.

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist for two years, unmarried. Salary £175 per annum, rising £5 a year, with furnished quarters, attendance, coal, gas, garden produce, and washing.

Leeds Public Dispensary.—Two Junior Resident Medical Officers for one year. Salary £100, with board and lodging, and an increase of £10 on re-appointment.

Leicester Infirmary.—House Physician for 12 months. Salary £100 per annum, with board, apartments, and washing.

Liverpool Stanley Hospital.—Junior House Surgeon. Salary £70, with board, residence, and washing.

Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary at the rate of £60 per annum, with board, attendance, and washing.

Monkwearmouth and Southwick Hospital, Sunderland.—House Surgeon, unmarried. Salary £80 per annum, with board, residence, and washing.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—Assistant House Surgeon for six months. Board, apartments, and washing provided, and at least £10 given as an honorarium.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £140 per annum, all found except board.

Radcliffe Infirmary, Oxford.—Honorary Assistant Surgeon.

Royal Boscombe and West Hants Hospital, Bournemouth.—House Surgeon. Salary £60 per annum, with board, lodging, and washing.

Royal College of Surgeons of England.—Examiner.

Royal Free Hospital, Gray's Inn-road, London.—Assistant Surgeon for out-patients.

Royal Hospital for Children and Women, Waterloo Bridge-road, London.—Assistant Surgeon.

Royal Portsmouth, Portsea, and Gosport Hospital.—House Surgeon for one year, unmarried. Salary £100, with board and residence. Also Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

Salford Union.—Assistant Medical Officer, male, at the Union Infirmary, Hope, near Eccles, for one year. Salary £150, with furnished apartments and attendance (no rations) in the Infirmary. Apply to the Clerk to the Guardians, Union Offices, Eccles New-road, Salford.

Salop Infirmary, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

Swansea General and Eye Hospital.—House Physician for twelve months. Salary £75, with board, apartments, and washing.

Taunton and Somerset Hospital, Taunton.—Assistant House Surgeon for six months. Salary at the rate of £60 per annum, with board, lodging, and laundry.

The Chief Inspector of Factories gives notice of vacancies for Certifying Surgeons under the Factory Acts at Darwen, in the county of Lancashire; and at Exmouth, in the county of Devon.

Victoria Central Hospital, Liscard.—Specialists for the Ear, Nose, and Throat, and a Gynæcologist.

Victoria Hospital for Children, Queen's-road, Chelsea.—House Surgeon for six months. Honorarium £25, with board and lodging in the hospital.

Western General Dispensary, Marylebone-road, London.—Two Honorary Surgeons.

West Kent General Hospital, Maidstone.—House Surgeon, unmarried. Salary 100 guineas, rising 10 per annum to 120 guineas, with board and residence. Also Assistant House Surgeon for six months. Honorarium at the rate of £50 per annum, with board and residence.

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—Assistant House Surgeon for six months. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided.

Worksop Dispensary and Victoria Hospital, Worksop.—House Surgeon and Dispenser. Salary £150 per annum, with rooms and attendance.

Births, Marriages, and Deaths.

BIRTHS.

Holden.—On Dec. 13th, at Castle Hill, Reading, the wife of George Herbert Rose Holden, M.A., M.D. Cantab., of a son.

Mackintosh.—On Dec. 14th, at Lilybank, Bishopbriggs, the wife of Hugh J. Mackintosh, M.B., C.M., of a son.

Tait.—On Dec. 15th, at Highbury Park, the wife of Edward Sabine Tait, M.D., of a daughter.

MARRIAGES.

Bennett—Tangye.—On the 18th Dec., at Carr's-lane Chapel, Birmingham, by the Rev. J. H. Jowett, W. E. Bennett, F.R.C.S., of 22, Broad-street, Birmingham, son of Wm. Bennett, Hertford-place, Coventry, to Mary Ethel Tangye, only daughter of George Tangye, J.P., of Heathfield Hall, Handsworth, Birmingham.

Gurney—Williams.—On Dec. 15th, at St. John's, Notting-hill, Alexander C. Gurney, M.B., of Gildredge-road, Eastbourne, to Minnie Hallyburton, third daughter of the late Major-General H. E. T. Williams, 108th Regiment, of Ladbroke-gardens, W.

Harston—Harston.—On Dec. 12th, at the Cathedral, Hong-Kong, George Montagu Harston, M.R.C.S., L.R.C.P. Lond., second son of George A. Harston, of Wentworth House, Harrogate, to Mabel Elsie, daughter of E. F. B. Harston, of Trebovir-road, South Kensington, London.

Linington—Sims.—On 15th inst., at All Saints, Norfolk-square, W., by the Rev. William Boyd, M.A., William West Linington, F.R.C.S. Eng., of Folkestone, son of Rev. W. A. Linington, Nightingale-lane, S.W., to Nina Sims, the eldest daughter of Charles Sims, Esq., L.D.S. Eng., of Edgbaston,

DEATHS.

Dunlop.—Near Lagos, West Africa, Charles Seymour Strickland Dunlop, L.R.C.P., M.R.C.S., Assistant Medical Officer Government Railways, eldest son of Andrew Dunlop, M.D., Jersey, aged 27 years.

Laver.—On Dec. 14th, at Rutland Park, Sheffield, Arthur Henry Laver, M.D., aged 50 years.

Morison.—On Dec. 14th, suddenly, at Edinburgh, Donald Morison, M.D., English Presbyterian Mission, Bengal.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE MEDICAL PROVIDENT LEAGUE."

To the Editors of THE LANCET.

SIRS,—The question now before the General Medical Council respecting the propriety of medical men employing canvassers and touts in connexion with private clubs cannot fail to expose a number of specific cases which have too long been allowed to remain uninvestigated. And if it is seen that the Council entertains more than a mere "pious opinion" upon this question of ethics the profession at large, I am sure, will be much benefited. It is in the methods of *private* clubs that abuse is most apt to occur and procedure most likely to become unprofessional. If the association of a medical man with a friendly society employing collectors and canvassers is objected to, what can be said of a medical man who himself employs 30 or 40 collectors, many of whom, be it remembered, are agents for other associations as well, whose remuneration is in direct proportion to their success in procuring new members and to the amount of money collected? What can be said of the man who promises his agents the appropriation of the weekly subscriptions for the first two months after joining and 25 per cent. of all moneys collected subsequently?

There is yet another aspect of this sort of practice allowing of the introduction of a system of "sweating" and affecting that most unfortunate section of the profession—the moneyless "qualified assistant" —which may be discussed in this connexion. In our larger towns the penny-a member private medical clubs worked upon the system alluded to soon become so extensive as to be altogether beyond the capacity of a single practitioner to attend to. Several needy assistants are engaged and each has a separate district assigned to his management. Thus the principal is altogether relieved of the unpleasant work so frequently associated with club practices, while he is left to reap all the pecuniary benefits. Of course, assistants are paid a salary, but it will be generally found that such arrangements are made that the fees received from any private practice, which the assistant is encouraged to work up, are amply sufficient to pay all the expenses incurred and leave even a substantial surplus for the pocket of the "club doctor."

I am, Sirs, yours faithfully,

COMPTE RENDU.

Hull, Nov. 11th, 1900.

A WALKING MACHINE FOR PARALYTIC OR OTHERWISE DISABLED PERSONS.

WE have received from Mr. George Thomson, 40, Weaver-street, Glasgow, an illustrated description of an apparatus which he has patented under the name of a walking machine for paralytic or otherwise disabled persons The action of it may obviously be compared to that of a pair of crutches which are slid along the ground progressively and not lifted in the ordinary way alternately with each step that the user takes. The machine consists of a frame, preferably rectangular, composed of four standards or legs connected together by stays at top and bottom on three sides, leaving the fourth space open for the user to enter within it, and fitted with adjustments for varying its height and width The lower end of each of the four standards or legs carries a rubber-tyred castor A crutch to support the user is adjustably fitted on the top stay on each side of the machine, and it is so mounted that its position is capable of variation within wide limits As the frame stands upright on four castors it evidently has considerable stability, and infirm or helpless persons would probably find it useful on many occasions for moving about. It is, in fact, somewhat analogous to the old-fashioned children's "go-cart."

"HAVE MATERNAL IMPRESSIONS ANY EFFECT ON THE FŒTUS IN UTERO?"

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Stuart-Menteath's letter in THE LANCET of Dec. 15th the following facts may interest him. Some 15 years ago I was an ardent fancier and breeder of pigeons and visited the pens of a well known north country fancier to see his stock. He was not a scientific man and the word "atavism" would have driven him to his dictionary. His pens consisted of the usual house opening on one side into a large wire-netting inclosure, the whole structure being divided into five or six compartments, each containing a section of the house and of the inclosure. He complained to me that for some reason—to him unknown—all his birds in the end pen threw young deficient in colour and with a tendency, though he did not express it in these terms, to albinism. The free side of this pen looked on to a lawn, and on inquiry I learnt that this lawn was used almost exclusively for drying the household linen, and that for most days in the week the grass was covered with sheets, &c., put out to bleach in the sun. He also told me that he found when penning pouters in the next compartment to either Turbits or Jacobins, I forget which, the latter birds threw young quite useless for show as they had pouter markings, and he asked me if the proximity of the pouters could possibly be the cause; he did not think it could be so. As my friend was a successful exhibitor in the pigeon shows, having on one occasion at least taken the Crystal Palace Cup (the Columbarian blue riband), and a frequent judge at shows, his management of his own stock of birds entirely precludes any possibility of tainted blood in his breeding pens. That belief in the effect of maternal impressions is of ancient date is apparent from the Biblical account (Gen. xxx.) of how Jacob by means of a trick despoiled his father-in law of the best of his flocks and herds, though, of course, this is not evidence as to the correctness of the belief.

I am, Sirs, yours faithfully,

NORMAN DAVIS, M.D. Durh.

Buntingford, Herts, Dec. 14th, 1900.

"A SUGGESTION FOR THE UNIVERSITIES OF OXFORD AND CAMBRIDGE."

To the Editors of THE LANCET.

SIRS,—The assurance of your correspondent with the lengthy *nom de plume*—if he could even for one moment be taken seriously—is simply astounding. By his proposal he would at once reduce Oxford and Cambridge to the level of examining boards and if this should be done in the matter of medical degrees why should it stop there? Why not in other faculties? Why should not laboratories, schools, colleges, residence, the social life and intercourse, and all that goes to make up the charm of *real* university life and to enhance the value of an Oxford or Cambridge degree, be done away with? And where would be the justice in his proposal to *bonâ fide* graduates—men who have given their time and means and many their life-work to their Alma Mater and who have learnt to love and reverence her with all her hoard of cherished and time-worn traditions? Does he suppose that these men would welcome—would ever permit a host of strangers—outsiders, too often with little better education and little more social standing than a Board school education imparts, to claim a degree simply because they came begging for it with sufficient professional education to pass the final and with the necessary fees in their hands? No grace would ever be vetoed in the senate with more unanimity. The *sang froid* with which your correspondent parades his proposal almost induces me to think that he has not only passed his first half century but that he is nearing the completion of his second. I would that Oxford and Cambridge would take example from Trinity College, Dublin, and enforce the taking of an arts degree before graduation in medicine, and that all three universities would take a leaf out of the book of the Royal University of Ireland and not grant their diplomas in public health to any but their own graduates

I am, Sirs, yours faithfully,

Dec. 17th, 1900 M A. CANTAB., M.A., M.D. DUBLIN.

*** The University of Oxford does enforce the taking of an arts degree before graduation in medicine.—ED. L.

THE BIRMINGHAM CONSULTATIVE MEDICAL AND SURGICAL INSTITUTION.

To the Editors of THE LANCET.

SIRS,—In that town where Egyptian mummies are turned out in a week to resemble the products of a thousand years and where ancient armour worn by some imaginary ancestor may be "made to measure while you wait," we must, I suppose, be flattered to think that they have given a member of our profession fully five years to become a "consultant" At college one was always taught to look upon a consultant with something approaching awe, to regard him in the light of a man who had grown old and white with years of patient toil and careful study ere he had reached that lofty pinnacle of fame and respect. But in Birmingham all this seems to have changed. "Consultants at the shortest notice!" will probably soon be the leading advertisement in the enterprising city. But the experienced—the "wise men" of the profession—what will *they* be called in this new nomenclature? Possibly they will be known in the coming century as "street doctors" After all, "what's in a name?"

I am, Sirs, yours faithfully,

WILFRED KINGDON.

London, N.W, Dec. 18th, 1900.

"ORCHITIC EXTRACT."

To the Editors of THE LANCET.

SIRS,—In answer to your inquirer "Prostate," and seeing your remarks in THE LANCET of Nov. 17th, I would like to give you my experience of the above. Two years ago a patient came to me complaining that he had lost the power of "sexual function"; he was only 35 years old, and after trying the usual tonics, &c, I gave him 10 grains of the above in tabloids three times a day and continued this for three months with the following results. He lost flesh, became very thin, had flabby muscles, and, as he expressed it, was too tired to do anything, and there was no improvement in any way from what he was suffering from. I discontinued this treatment, gave him tonics and cod liver oil, and he became strong and well again as far as his health was concerned. I tried the extract again with the same result but in a more pronounced form; finally, I left it off and reverted to tonics, &c. He regained his general health and former condition with the exception of the one point, which still remains.

I am, Sirs, yours faithfully,

A. CHURCHWARD, M D. BRUX., &c.

THE TREATMENT OF BROMIDROSIS.

To the Editors of The Lancet.

Sirs,—Could any of your readers inform me whether there is any treatment likely to do good in combating most offensive perspirations exuding all over the skin of a young lady, aged 23 years, of sound constitution and with no special history? The slightest exertion brings on these perspirations, more especially, of course, in the summer, and they are so bad as to be considerably interfering with the young lady's happiness and prospects in life. My patient is a good-looking woman, of charming manners, but her prospects of marriage are very poor whilst suffering from such an affliction.

I am, Sirs, yours faithfully,
Dec. 17th, 1900. G. P.

THE DANGERS OF COLONIAL APPOINTMENTS.

To the Editors of The Lancet.

Sirs,—I notice in The Lancet of Dec. 8th an advertisement for assistant medical officers to attend on Government staff constructing railway in West Africa. May I ask what diseases, other than those that may attack one in Britain, a man may risk out there, and in what other ways he may become incapacitated for work? The pay offered is good, but one naturally would like to know is it worth the risk? Could you inform me of the probable costs that would be incurred (1) in outfit suitable to the climate; and (2) costs incidental to living in such a country. The advertisement states that free quarters would be given. Does that mean board and lodging, or simply lodging alone? Knowing no one who can give me information about the matter, I therefore appeal to you. Apologising for troubling,

I am, Sirs, yours faithfully,
Dec. 8th, 1900. Ten[illegible]omy.

FIRST AID WITH A VENGEANCE.

To the Editors of The Lancet.

Sirs,—I was visiting a patient the other morning, and a lady staying in the house had, a few minutes before my arrival, fallen down stairs and badly sprained one of her ankles. I obtained some strapping and applied it to the joint, and she expressed herself gratified for my help and the support the strapping gave. On the following day I made inquiry how the ankle was and received an answer that she would not trouble me to see her, she was being treated by the "butler," who was well acquainted with massage. "First aid" this, with a vengeance.

I am, Sirs, yours faithfully,
Dec. 13th, 1900. Practitioner of 30 Years' Standing.

VACCINATION FEES.

To the Editors of The Lancet.

Sirs,—Would you kindly say if a public vaccinator is entitled to the 1*s*. birth fee for cases vaccinated by him privately, when such children are under the age of four months? *Vide* Local Government Board Orders of October 18th, 1898, Art. III., Sec. (1*a*). My guardians refuse to pay such fees. I am, Sirs, yours faithfully,
Dec. 10th, 1900. Public Vaccinator.

⁎⁎⁎ The vaccinations in question were not performed by the public vaccinator in his official capacity of public vaccinator, and he is therefore not entitled to the birth fee, as the cases in dispute had not been entered on the vaccination officer's birth lists.—Ed. L.

"THE CASE OF DR. PATRICK QUINLIVAN."

The following additional subscriptions have been received towards the fund for the family of the late Dr. Quinlivan:—Mr. and Mrs. F. J. Hamby, £1 1*s*.; Dr. Giusani, £1; Dr. Lehane, £1 1*s*.; and Dr. Dunn, 10*s*. 6*d*.

THE "SOLIS" PIPE.

We have received from Mr. A. Wyllie of 39, York-road, Upton-park, London, E., a patent pipe the object of which is to prevent saliva saturated with nicotine from entering the mouth and also to keep the tobacco dry. The pipe is similar in appearance to an ordinary one, but the bottom of the bowl is bored out and replaced by a plug. Through this plug passes a screw on the top of which is an absorbent plug which presses lightly on a projecting rim within the pipe just above the upper surface of the plug which closes the bottom of the bowl. The smoke and nicotine thus enter a chamber below the tobacco. The object of the screw is to regulate the draught. Although apparently complicated, this pipe is very simple in construction. It may possess all the merits which its inventor claims for it, and it looks as if it does, but the experience of smokers is that some men can manage any pipe and some men can manage none.

"TREATMENT OF CONSUMPTION BY ARSENIC."

To the Editors of The Lancet.

Sirs,—In reference to the inquiry of "L.R.C.P. & S. I." in The Lancet of Dec. 15th for the manufacturers of sodium kakodylate and the solutions for the Gautier treatment, we beg to inform him that we have made and supplied them for several months. If he will communicate with us we shall be pleased to answer any inquiries.

Yours faithfully,
Oxford-street, W., Dec. 18th, 1900. Squire and Sons.

MUSICAL SURGERY.

The multitudinous comic journals that of late years have sprung up like mushrooms are not always humorous, but sometimes they do contain jokes, properly so-called, and not merely verbal inanities. The following really humorous little jest is taken from a recent issue of *Tit-Bits*:—

> Landlady: "Beg pardon, sir, but did I understand as you were a doctor of music?"
>
> Musician: "I am, ma'am; why?"
>
> Landlady: "Well, sir, my Billy 'ave just been and broke 'is concertina, and I thought as 'ow I shud be glad to put a hodd job in yer way."

There is, of course, nothing new under the sun, and this may be an arrant "chestnut," but we do not remember having met with it before.

"ARSENIC IN WHISKY?"

Messrs. Mackie and Co., distillers, of 217, West George-street, Glasgow, point out in reference to the annotation under the above heading in our columns last week that no glucose or substitutes are employed in the manufacture of Scotch whisky whatever. Further, in their distilleries they state that they are licensed to distil from malt only, and as two excise officers are resident at each distillery all the year evasion of the law is impossible even if desired. We may observe that our remarks were not directed to Scotch whisky in particular but to whisky in general. We are glad to learn of the course which Messrs. Mackie and Co. state that they adopt, but they cannot deny surely that much of the ordinary whisky sold is a blend of malt and corn spirit. It was from this fact that suspicion fell upon whisky as possibly containing arsenic, a suspicion which, according to our experiment, is unfounded.

FIRST AID ON RAILWAYS.

The directors of the London and South-Western Railway Company have recently decided to offer, annually, a valuable Challenge Shield and silver medals for competition between the teams chosen from the ambulance classes, which have been organised at many of the principal stations throughout the railway in the past two years. The intention of the directors is to induce their employés to join the ambulance classes. It may be stated that since Jan. 1st, 1899, 636 members have obtained the St. John Ambulance Association certificates of efficiency in first aid. The directors liberally bear the entire outlay in the working of the classes.

THE CONDITION THREE YEARS AFTER OPERATION OF FIFTY SUCCESSFUL CONSECUTIVE OVARIOTOMIES: A CORRECTION.

To the Editors of The Lancet.

Sirs,—In your last issue, p. 1721, first column, lines 7 and 8, the words "December, 1900," should be omitted and the sentence in which they occur should not be in parenthesis. The cases referred to were last seen by me shortly before the paper was read on Dec. 11th, 1899. The sentences in parenthesis were added when I sent the paper to you in September of this year.

I am, Sirs, yours faithfully,
Portman-street, W., Dec. 17th, 1900. John D. Malcolm.

SURGICAL PATHOLOGICAL SPECIMENS.

To the Editors of The Lancet.

Sirs,—Please allow me through The Lancet to ask my fellow practitioners where I can get a good complete set of surgical pathological specimens and a second-hand microscope. I am reading for a surgical examination. I am, Sirs, yours faithfully,
Dec. 10th, 1900. Patella.

◆

Signor S. Bocca.—We are aware of no work dealing with the associated effects of the poisons. The suggestion of associated effects has arisen out of the epidemic of peripheral neuritis at Manchester. The subject is therefore comparatively new and doubtless will be investigated thoroughly in due course. A valued work on the subject of poisons, their effects and detection, is that by Mr. Wynter Blyth, published by Charles Griffin and Co., Exeter-street, Strand, London.

Suburban.—It is true that some members of the medical profession do not set a high value on their services, but the abuse in connexion with medical aid associations is more extensive than is implied in this admission.

A Subscriber to The Lancet, *&c.*, *F. R. C. S.*, *R. C. O.*, and others are thanked for their letters. We do not accept advertisements which on their face propose to sweat medical men, and we are always pleased when our readers will help us by giving us such information.

W. H.—Our correspondent's statement is too generalised and vague. If he will forward us some specific instances of the behaviour to which he alludes we should be more able to give an opinion upon the matter.

A Nurses' Lecturer.—Our correspondent need have no fear in recommending nurses to seek the membership of the Royal British Nurses' Association.

Streatham.—The removal of tattoo marks can sometimes be effected. A surgeon might be consulted.

T. P. J. C. has not favoured us with his name and address.

Bill.—Our correspondent should consult his solicitor.

ERRATA.—In Dr. Poore's Purvis Oration on Dietetic Problems, published in THE LANCET of Dec. 15th, the words "Royal Society" (p. 1715, col. 2, line 60) should be *Royal College of Physicians of London*; "Cheadle" (p. 1715, col. 2, lines 67, 75) should be *Chepmell*; "Taylor" (p. 1716, col. 1, line 53) should be *Thiele*.

TUESDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

WEDNESDAY (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

FRIDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.).

SATURDAY (29th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

During the week marked copies of the following newspapers have been received: *Behar Herald (Bankipore), South Wales News, Hull Daily Mail, Manchester Courier, Westminster Gazette, West Morning News, Norfolk Daily Standard, Leeds Mercury, Scotsman, Newcastle Daily Chronicle, York Daily Herald, Glasgow Herald, Nottingham Daily Express, Yorkshire Post, Times of India, Pioneer Mail, Scarborough Mercury, Kent Messenger, Liverpool Daily Post, Western Mail, Birkenhead News, Citizen, Architect, Builder, Harrogate Advertiser, Crewe Guardian, Bradford Observer, Eastern Daily Press, Bristol Mercury, Birmingham Gazette, West Bromwich News, Bath Argus, New York Herald, Sheffield Daily Telegraph, Evesham Standard, Carlisle Journal, Swansea Herald, Rugby Advertiser, Coventry Herald, Gloucester Journal, Essex Herald, Stafford Advertiser, Worcester Chronicle, Dundee Advertiser, Somerset Gazette, Plymouth News, Retford Herald, Wolverhampton Express, Modern Society, Exeter Times, Yeovil Advertiser, Mining Journal, Brisbane Courier, Reading Mercury, Local Government Chronicle, City Press, Hertfordshire Mercury, Surrey Advertiser, Public Health Engineer, Local Government Journal, Luton News, West Sussex Gazette, Courrier de la Presse (Paris), Herne Bay Press, Warwick Times, Grimsby Daily Mail, Standard, Hyde Reporter, Northern Echo, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Dr. F. P. Atkinson, Kew; Dr. J. M. Atkinson, Lond.; Mr. F. Alcan, Paris; Dr. D. A. Alexander, Leek; Apollinaris Co., Lond.; Messrs. Allen and Hanburys, Lond.; Archbishop's Assyrian Mission, Secretary of; Mr. H. St. A. Agate, Dartford; Dr. B. Addenbrooke, Kidderminster; Messrs. Allen and Hanburys, Lond.; Ancoats Hospital, Manchester, Secretary of.

B.—Messrs. Boot and Son, Lond.; Dr. P. G. Bell, Glasgow; Messrs. W. Foster Brown and Co., Montreal; Dr. D. F. Brown, Barnton: Sig. S. Bocca, Italy; Messrs. An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Bradshaw Lecture

ON

THE ASSOCIATION OF INGUINAL HERNIA WITH THE DESCENT OF THE TESTIS.

Delivered before the Royal College of Surgeons of England on Dec. 12th, 1900,

BY JOHN LANGTON, F.R.C.S. ENG.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; LECTURER ON CLINICAL SURGERY AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL, ETC.

MR. PRESIDENT AND GENTLEMEN,—The first lecture under the Bradshaw bequest was delivered 18 years ago by the late Sir James Paget who since the last lecture by Mr. Howse has passed away full of years and full of honour. From whatever aspect we view his career—be it his professional, scientific, or his *deeply religious life*, or be it his untiring energy, his ceaseless work, or his never failing courtesy—all must feel that he fully upheld the highest traditions of our profession and lived his life a noble example to us and a pattern for all time. The title of his lecture, as many here will recollect, was "Some New and *Rare Diseases.*" I cannot claim such a novel subject for my lecture on "The Association of Inguinal Hernia with the Descent of the Testis," for it is a subject so old that it claims its centuries of literature, it is so common that it affects probably not less than 5 per cent. of the entire population at all ages of life.

The descent of the testis is a developmental process which exerts a dominant influence as a cause of hernia in infants, an influence, however, less powerful as age advances. The journey of the testicle from its original site of development below the kidney to its ultimate destination in the scrotum materially weakens the lower abdominal walls, and thus contributes in no small extent to the extrusion of some of the abdominal viscera, especially if associated with a congenitally elongated mesentery. This want of parietal integrity is chiefly manifested in the early periods of life, but the weakness left by the passage of the testis exists to a greater or less degree throughout life and thus acts as a predisposing factor of hernia at all ages. *Ab initio* the testes are developed in the lumbar regions below the kidneys, and subsequently make their descent about the seventh or eighth month of intra-uterine life towards the scrotum which they have usually reached before birth The left testis descends three weeks in advance of its fellow, so that the complete developmental processes have usually been attained on that side at birth, whereas those on the right side are not complete. Many dissections have been made by Camper, Paletta, Schreyer, Seiler, and others who have demonstrated a failure in the closure of the vaginal process of the peritoneum, amounting on the right side to 21 per cent., on the left side to 13·5 per cent., and on both sides to 35 per cent.[1] It is noteworthy that frequently, probably more often than not, the processus vaginalis is unclosed to a greater or less extent at birth without the occurrence of any protrusion, thus affording a reasonable inference that a hernia does not exclusively depend on the patency of this peritoneal prolongation. At a later period I shall call attention to the fact that the vaginal process of the peritoneum may be completely patent throughout life without the occurrence of a hernial excursion. The more frequent failure at birth of the right vaginal process explains the large preponderance of congenital hernia on the right side as compared with the left. The descent of the testis is accomplished in part by the greater development of the upper part of the body, in part by a vital process, but chiefly by the action of the gubernaculum testis.[2] The gubernaculum, situated between the peritoneum and the psoas muscle, is attached by its upper end or apex to the testis, while its lower end frays out like a goose's foot. One of these lower processes is attached to the pubic crest, another, and by far the largest and strongest part, passes into the scrotum, while the third portion is attached to Poupart's ligament close to the inguinal canal. Sometimes accessory prolongations can be demonstrated passing to the saphenous fascia over Scarpa's triangle and more rarely to the perineum, where it becomes lost in the tissues about the region of the anus and the ischial tuberosities. These aberrant fasciculi account for the abnormal positions in which the ectopic testes are from time to time found.[3]

The testis is invested in front by the peritoneum and in its descent to the scrotum carries with it a peritoneal process which precedes it and eventually forms the tunica vaginalis testis. This serous prolongation does not appear to be dependent on the testicular descent, for instances are not rare in which the testis is completely retained but with the vaginal process lying complete in the scrotum and completely shut off from the general abdominal peritoneal cavity. Specimens illustrating this are seen in most of the museums, and an especially interesting one is in the University College Hospital museum, which was removed from a cryptorchid, showing a well developed processus vaginalis in each half of the scrotum.[4] I have on many occasions seen instances of a long vaginal process containing more or less ordinary hydrocele fluid far in advance of a partially descended testis.

The upper portion of the peritoneal process pushed in front of the testis in its descent into the scrotum normally becomes obliterated by the closure of its canal from the internal abdominal ring to the upper part of the testis and subsequently dwindles into a long, slender cord, whilst the lower portion of the peritoneal pouch forms the tunica vaginalis testis. Failure in the complete developmental process often occurs with the result that the testicular sac communicates directly valvularly with the abdominal peritoneal cavity. A hernia descending through the unobliterated portion into the cavity of the tunica vaginalis testis is called a "congenital hernia" or preferably "a hernia into the cavity of the tunica vaginalis testis." The term "congenital hernia" lacks definiteness, as it may be interpreted in two senses, either that the hernia dates from birth, which is not true, or that it is dependent upon an arrest of development of congenital origin, which is true. This nomenclature should be strictly confined to the anatomical position of the hernia and not to its assumed chronological appearance

In acquired inguinal hernia the protrusion with its sac lies in front of the chord and the testis, the sac being loosely connected with the chord, from which it can be easily detached. In congenital hernia, on the other hand, the constituents of the chord are firmly attached to the sac, so that it needs careful dissection to remove the thin membrane which forms the congenital sac and so adds much difficulty in the operation for the radical cure of this variety of hernia.

Sir William Lawrence in his still admirable "Treatise on Ruptures"—a term, by-the-bye, to which much exception may be taken—and other writers also, felt the inappropriateness of the word "congenital," for the former states in a footnote that in a limited sense the term "congenital hernia" may be condoned, but he further says: "I cannot understand for what reason Mr. Pott and some others have exchanged this for the appellation *congenial* which according to its common use and acceptance must be perfectly absurd as applied to this or any other form of rupture."[5]

The second variety is the *funicular hernia* in which a protrusion takes place into the vaginal peritoneal process closed only at its lower part and consequently separate from the testicular sac, the upper part being still patent.[6] The following diagrams represent the closure of the vaginal process from below upwards but leaving the upper portion still patent into which a hernia descends. In Fig. 1 the lower end of the vaginal process has commenced to be narrowed but still communicates by a large neck with the cavity of the tunica vaginalis testis. This is the commencement of the closure of the canal In this form there is often some fluid which is reduced easily *pari passu* with the intestine into the abdominal peritoneal cavity. In the second stage the funicular sac is further separated from the testis with its tunic but it still communicates with its cavity by a longer and narrower canal. In this stage fluid is also frequently present in the sacs, and when the taxis is applied it is reduced gradually at first, but as the closure progresses the lumen becomes so narrow and tortuous that the fluid is irreducible. The narrow canal becomes more elongated and eventually closed, so that no communication now exists between the testicular and funicular sacs. The long white fibrous cord connecting these two sacs is called the filament fibreux of Cloquet, which frequently encloses a small, narrow canal which at some later period may become expanded by a collection of fluid and form an encysted hydrocele of the chord in Fig. D. This long canal, however, normally becomes completely closed and is converted into a white fibrous cord which is easily recognisable by dissection or during operation.[7] The funicular sac, although usually long, sausage-shaped, may be constricted annularly in one or more places, so as to give the appearance of one or more bulges in a hernial protrusion. In operating for the radical cure we not infrequently come across an annular thickening, usually about the middle and narrowest part of the process, and in two instances I have come across a diverticulum in the sac immediately above the constriction. It is a moot point as to the cause of this ring of fibrous tissue. By some it is ascribed to the displaced neck of the sac, but I think it is due to the attempted closure of the lower part of the vaginal process.[8]

---

[1] Camper reports that in 52 cases the vaginal process of the peritoneum was patent in 11 instances on the right side, in six instances on the left side, and in 23 cases on both sides Seiler found the canal still unclosed in *four* cases on both sides, in five on the right side, and in four on the left side out of a total number of 21 cases.

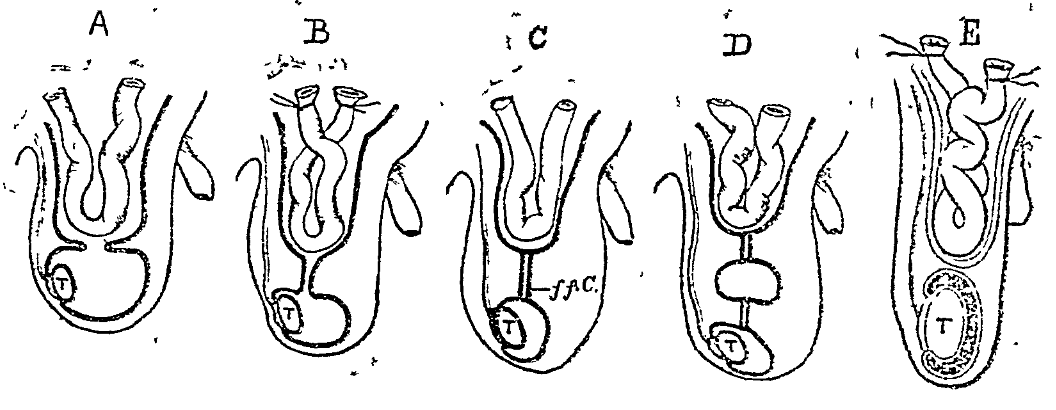
FIG. 1.



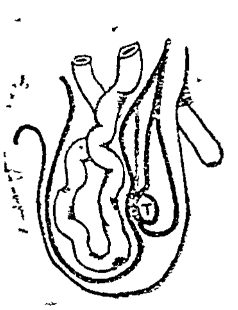
(*After Félizet.*)

Congenital hernia: second variety.—Into the unclosed funicular process and its method of closure—funicular hernia.

a. Hernia into the funicular process with a large patent neck communicating with the cavity of the tunica vaginalis testis. T. testis. *b.* Hernia into the funicular process with a long narrow canal communicating with the patent tunica vaginalis testis. *c.* Hernia into the funicular process connected by a long thin cord to the tunica vaginalis testis. *f.f.C.* Filament fibreux de Cloquet. *d.* Funicular hernia with an encysted hydrocele of the cord between it and the tunica vaginalis testis. *e.* Hernia into the funicular process—funicular hernia.

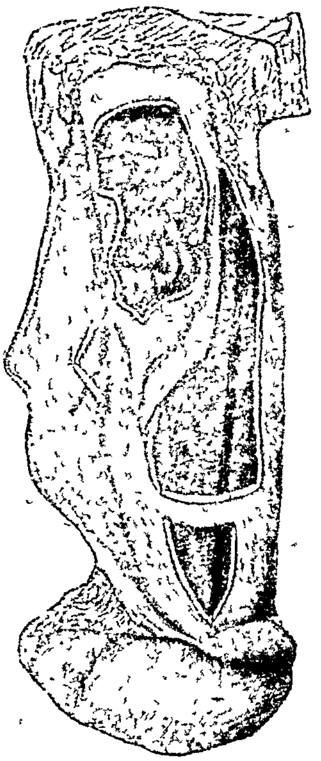
A third variety of congenital hernia known as infantile hernia is seen in an arrested development of the closure of the processus vaginalis except at the extreme upper part, so that the tunica vaginalis testis extends up to the inner ring, where it is closed, in which case a hernia may be protruded behind the process and then descend behind the tunica vaginalis testis to the scrotum, as in Fig. 2. Sometimes the abdominal terminations of the processus vaginalis may be patent, as in Fig. 4, so that it is not essential for this communication to be closed to constitute it an infantile hernia.

FIG. 2.



Congenital hernia: third variety.—Infantile hernia, in which the hernial sac and its contents lie behind the testis, invested by its elongated tunica vaginalis testis.

FIG. 3



Infantile hernia: St. Bartholomew's Hospital Museum, 2140b.

In Fig. 3 the funicular process of the peritoneum is closed at its extreme upper end at a level with the internal ring, but for the rest of its extent it remains as an oval tube. A hernia descending posteriorly to the inner ring has made its way behind the unclosed funicular process.[9] An infantile hernia, as before said, exists with a patent mouth in which a hernia has pushed a sac behind it and into which it is probable that a hernia has passed, as also into the anterior patent processus vaginalis In this instance it is evident that the infantile hernia was not the outcome of a closed vaginal process at the inner ring

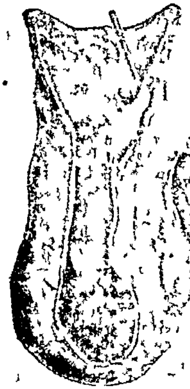
FIG 4



Congenital hernia third variety —Infantile hernia into a sac behind the cavity of a patent tunica vaginalis testis into which a hernia also passed

Another variety of infantile hernia is observed from time to time where the hernia, instead of continuing its descent behind the cord and testis, pushes itself forwards into the unclosed vaginal process, which on being opened reveals a convex tumour bulging the posterior wall forwards and occupying more or less of the vaginal sac This is without doubt one of the forms of the so-called encysted hernia of Hey and others, and its pathology has been described by Mr Lockwood in which he shows that it is a modified variety of the first form of infantile hernia

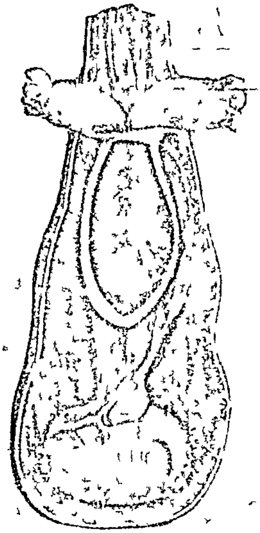
There is another form which may be included in the infantile herniæ but which presents such differences that it might be classified as a distinct variety of congenital hernia It consists of an oval fibrous sac which is pushed vertically downwards into an unobliterated vaginal process and attached by its neck to the inner ring The sac hangs free in the vaginal cavity and differs from the firm, fleshy, and globular sac of the variety just described In an illustration of Cooper's work (Plate xi) there is represented an oval fibrous sac containing a loop of intestine hanging by its neck in the cavity of an enclosed tunica vaginalis testis This is an encysted hernia

Some months ago I operated at St Bartholomew's Hospital for the radical cure on a young man who, we believed, suffered from an ordinary funicular hernia but with thicker walls than usual I opened what was thought to be the sac of the hernia, but I discovered that it contained about two ounces of ordinary hydrocele fluid in a sac which extended as high as the inner ring On evacuation of the fluid an oval sac of the size of a large olive was found hanging by its neck in the hydrocele sac The second sac, which was firm, fibrous, and thin, on being opened was found to be empty and it communicated by a large oval mouth with the abdominal peritoneal cavity At the time of the operation the sac was empty, but it had evidently contained some entero epiplocele The sac was dependent from the neck of the hydrocele sac and was placed immediately above and not behind the chord as seen in ordinary infantile hernia The case may by some be considered as an instance of an infantile hernia but its connexions, situation, and structure were so different from that usually considered as an infantile hernia, that it must clearly be relegated to a distinct variety of infantile hernia[10] My explanation of this specimen is that a large sac containing hydrocele fluid was a funicular hydrocele separated from the testicular sac and that into it had descended an invaginal hernial sac or an encysted hernia

Experience shows that hernia in male infants under six months is much more frequent than in females of the same age Inguinal hernia occurs eleven times more often in boys than in girls under the age of 12 months, the exact figures being 3215 infant boys to 290 infant girls These numbers refer to the date of the first application of the patients for relief and not to the date of the first discovery of the lesion The importance of differentiating these is at once apparent, as the first refers only to the age of examination by the surgeon when the patient is under the age of one year, and therefore cannot fail to be correct, whereas the second includes not only these but also all patients who come for relief at later ages and date the first occurrence of their hernia to birth, but whose statements cannot be accepted as absolutely reliable The proportion, as already stated, is under the first class as 15 males to one female while in the second class of patients who date their hernia from birth it is as 16 to one

Inguinal hernia in infant boys is three times more frequent on the right side than on the left, whereas in infant girls the two sides are nearly equal This disproportion between the two sides in boys is explained by Camper and others by the fact that the processus vaginalis is much more commonly patent in boys at birth on the right side than on the left The consistent preponderance of ruptured boys as against ruptured girls which repeats itself so persistently year after year in our records at the City of London Truss Society may be accounted for, firstly, in the structural weakness in the abdominal walls caused by the passage of the testis through them during intra uterine life, whereby the walls are unable effectually to resist the constant pressure from within, and, secondly, to the failure in the perfect occlusion at birth of the processus vaginalis

FIG 5



Encysted hernia Guy's Hospital Museum

The following table states the relative proportion of the frequency of hernia in each quinquennial period as given by the patients as the date of the first discovery of the hernia. It shows that during the first year of life hernia in boys reaches the high percentage of 15 22 of the total number, whereas in the case of girls it is only 8 55 per cent There must therefore be some other dominant cause of hernia in boys beyond the general tendency to hernia in both sexes and this factor is the descent of the testis

Children born prematurely are very liable to hernia at birth and, so far as my experience goes, the hernia is more frequently on both sides than when infants are born at full term The cause of this is not far to seek, as under these circumstances the vaginal processes are patent on both sides That inguinal hernia preponderates in infant life over other ages accords not only with our expectancy but also with statistics. The subjoined table corroborates this and thus supports the theory that the descent of the testis is largely responsible as an active cause of hernia. I have also appended a table for infant girls on the same lines as that for infant boys, and it shows the great numerical difference between the two sexes in the lessened aggregate and proportionate numbers in herniated females.

Retained, partially descended, and ectopic testes.—Herniæ are largely associated with testes which fail to descend to their normal position in the scrotum. Under such conditions they may be completely retained within the abdomen or they may be arrested in their descent within the inguinal canal or in the inguino-scrotal region. They may further be misplaced in regions outside their normal course and may be found in the thigh, perineum, and peno-pubal regions. Ectopic testes may be associated with a hernia, but this is of rare occurrence. If the testes have passed beyond the internal abdominal ring they are usually associated with a hernia, but they may be situated in any abnormal region without such association. In infants under 12 months of age one or both testes may be apparently retained within the canal, but a little traction will suffice to overcome the action of the cremaster muscle and thus enable us to bring them down to their normal position in the scrotum. Their range of locomotion is proportionately in excess of that in adults, and in health they are usually situated high up in the scrotum, being maintained in this position by the vigorous cremaster and dartos muscles.

Instances frequently occur of testes permanently retained in the canal without a hernia. This condition need not engage our attention so long as they are not associated with hernia, but it must be remembered that the two conditions often go together. It is stated, often authoritatively, that retained testes are liable in later years to become the seat of malignant disease. From my own experience in public practice, but especially in private, I believe this statement to be devoid of any foundation in fact, and on reference to the Registrar-General's reports my experience is fully corroborated. The opportunity of collecting any reliable statistics bearing on the frequency of hernia with malposition of the testis is not very ready, but I have no doubt that this non-association is not rare.

Misplaced testes, in which also must be included ectopic testes, though often dependent on different causes, should be classified under the anatomical positions which they occupy, as follows: (*a*) complete retention within the abdomen; (*b*) retention within the inguinal canal; (*c*) placed outside the external abdominal ring; (*d*) situated high up in the scrotum, in the inguino-scrotal region; (*e*) placed in a skin pouch in the cleft between the scrotum and the thigh without any dartos tissue (these are sometimes, though maladroitly, designated "cruro-scrotal testes," for these organs are neither in the thigh nor in the scrotum); and (*f*) ectopic testes placed in unusual positions by the action of an errant gubernaculum in the thigh, perineum, or peno-pubal regions or displaced by a hernia. I have examined the records of patients of whom careful notes have been taken, which reach a total of 7661 males who were the subjects of hernia, and I have not thought it expedient to chronicle a larger number, as the very largeness is apt to bewilder us, and, moreover, it does not ensure greater accuracy or afford us any additional knowledge. Of this number 4310 were situated on the right side, 2812 on the left side, and 539 on both sides. Statistics record that in 174 cases the testes were misplaced in the positions shown in the following table:—

TABLE IV.—*Giving an Analysis of the Different Situations in which Malposed Testes are found.*

Testes.	Right.	Left.	Double.	Total.
1. Completely retained in the abdomen	9	4	3	16
2. In the inguinal canal ...	24	15	13	52

5. Ectopic testes	2	—	—	2
6. Cruro-scrotal	2	1	—	3
7. Small testes placed normally in the scrotum ...	10	1	5	16
8. Malposed testes without hernia	2	8	—	10
	92	57	25	174

It is only in the first four and the last classes that the testes have been arrested in some part of their journey and have failed to reach their destination in the scrotum. These may be described as *misplaced testes* Classes 5 and 6 are *displaced testes* by an errant action of the gubernaculum testis; while in Class 7 the testes are small only but are situated normally in the scrotum. With the exception of the last class all the others were associated with hernia and small ill-developed testes. This table shows that in 16 cases the testes were completely retained within the abdomen, nine being on the right side, four on the left, while in three cases both testes were retained. In 52 patients the testes were retained within the inguinal canal and could not be extruded through the external ring; of these 24 were on the right side, 15 on the left, and 13 on both sides at once. In 73 instances the testis was situated immediately outside the external ring, in the inguino-scrotal region, the right side claiming 43 instances, the left side 27, and both sides three examples. In only two instances were fully developed testes placed at the mouth of the external ring, one on the left side and in one case on both sides The fifth and sixth classes of ectopic testis comprise only five examples, the right side claiming four cases and the left side one instance, while in the double division there is no representative. In 16 cases the testes were small and ill-developed in the scrotum, 10 being on the right side, one on the left, and five on both sides. In 10 cases the testes were malposed, two on the right side and eight on the left side. Probably this number does not correctly represent the relative frequency of misplaced testes, inasmuch as patients would not seek advice for this uncomplicated condition. In every class but one the right side claims the predominance of malposition of the testis, for this side has 92 instances against 57 in the left out of a total number of 149 cases, the proportion being 6 to 4 in favour of the right side. In nearly all cases the testes were small and ill-developed, most being soft and flattened and frequently more tender and more highly sensitive than fully-developed organs During operations I have frequently found that testes retained in the canal are relatively larger than those situated outside the canal or in the inguino scrotal region. This suggests that the retention within the canal is due to those organs being too large to pass through the outer ring.

[Mr. Langton proceeded to discuss the crural and perineal forms of displaced testis and he showed that in both varieties the right side of the body is much more frequently affected than the left; either of these displaced testes may be associated with a hernia He then proceeded:]

In hermaphrodites, or in those whose sex is doubtful, who are, however, mostly males, we occasionally come across cases of inguinal hernia on one or both sides associated with bodies usually irreducible in the situation of the external ring. The nature of these bodies although inferred cannot be considered proven unless examined microscopically.

It must not be assumed that all misplaced testes are associated with hernia, though this is usually so, but the hernia may be first noticed many years subsequently to the first discovery of the arrested organ. It is impossible to determine the first occurrence of the hernia, and I have therefore limited my statistics to definite data so as not to place too implicit a reliance on the inexact statements of patients.

CONGENITAL HERNIÆ.

Most patients with misplaced testes become at one time or another the subjects of hernia, but there are many whose testes are fully developed in the scrotum in whom the complete occlusion of the processus vaginalis has altogether failed or failed in part. Under these circumstances an extension may occur into this abnormal vaginal process, so that the hernia becomes associated with the testes which may be completely or incompletely developed.

Herniæ may have their origin at birth and they may occur at any age of life for the first time. It is therefore more accurate to classify these varieties of hernia according to their anatomical relations with the vaginal process of the peritoneum These should all be classified under the general heading of congenital hernia but made up of the following varieties: 1. Herniæ into the cavity of the tunica vaginalis testis which strictly includes the majority of so-called interstitial herniæ. 2. Herniæ into the funicular process which descend into the enclosed funicular process of the vaginal peritoneum. 3. Herniæ into a post tunica vaginal sac, commonly known as infantile herniæ, in which the protrusion is situated behind a dilated tunica vaginalis extending as high as the internal abdominal ring. In this class are included also the encysted herniæ which push before them an invaginated membranous septum into the cavity of an unclosed tunica vaginalis testis. These herniæ are all associated with some anomaly in the closure of the vaginal process.

Hernia into the cavity of the tunica vaginalis testis is one of the most common varieties of congenital hernia and may occur for the first time at any period of life, from birth to extreme old age. In infants under the age of 12 months the position of the hernia can only be conjectured, for an exact diagnosis can only be made on dissection or operation. Protrusions in children usually consist of intestine, since the omentum is so ill-developed that it is rarely able to descend into the sac. Personally, however, I have little doubt that in nearly all cases of hernia in children under six months of age the hernia is into the cavity of the tunica vaginalis testis. At a later period of life, when the protrusion descends into the scrotum, it surrounds the testis as completely as does the fluid of an ordinary vaginal hydrocele. Under these circumstances the hernia forms a globular swelling within which the testis lies imbedded, so that it cannot be detected until the intestine or omentum has been reduced, the testis often being small and ill-developed. The scrotal tumour in these cases is so characteristic that the diagnosis is made without difficulty. The reduction of the hernia is often difficult and attended with a sickening pain and some faintness, partly due to reduction through a narrow fibrous neck and in part to the pain caused by the manipulation of a sensitive ill-developed testis.

The following table has been drawn up recording the percentages of hernia into the cavity of the tunica vaginalis at the time of the patient's first application for relief, arranged in quinquennial periods of life on the right and left sides respectively In this table no hernia has been included unless it fulfils all the clinical features of this variety of congenital hernia There is little doubt that the percentage of congenital hernia in early infancy would be largely increased if the table represented the ages at which the hernia was first discovered. No such table, however, would be accurate, inasmuch as it would be a record of patients' statements of the first appearance of the hernia.

TABLE V.—*Giving the Percentages of Cases of Hernia into the Tunica Vaginalis Testis, as they occur on each side in the various Quinquennial Periods of Life.*

Ages.	Right.	Left.	Ages	Right.	Left.
0—1	2·3	2·4	31—35	1·3	1·0
1—5	3·6	4·4	36—40	0·67	0·81
6—10	8·3	10·0	41—45	0·33	0·42
11—15	9·4	8·5	46—50	0·20	0·25
16—20	17·2	16·0	51—55	0·47	0·40
21—25	4·08	3·05	56—60	0·53	0·17
26—30	1·1	1·2			

Reference to these tables shows that this variety of congenital hernia takes place at every age, although, as might be expected, it gradually decreases as age advances. It is observed that the percentage rapidly increases from birth till the lustrum of 16 to 20 years, after which it rapidly declines, so that at 60 years of age the percentage is as low as 0·75 of the total number. It is not improbable that the numbers of the later periods of life are recrudescences of this disease in early life, and it is probable that the occurrences of this disease in later life are only reappearances of an earlier lesion. Hernia into the cavity of the tunica vaginalis testis is nearly equal on the two sides throughout life, the proportion being 49·58 per cent. on the right side and 48·60 per cent. on the left side. Out of a total number of 8342 cases of right inguinal hernia 227 were examples of the first form of congenital hernia, and of 5263 patients the subjects of left inguinal hernia 125 were instances of congenital hernia, or in the proportion of nine cases on the right side to eight on the left The importance of the recognition of this variety of hernia is not inconsiderable as the probability of the obliteration of the vaginal process is not hopeful, and especially so in the unclosed canal of Nuck. Often the hernia appears to be cured, especially when the patient is under puberty, but the cure is only apparent and due to the narrowing of the serous canal to such an extent as to prevent the descent of any hernia but not to real obliteration.

In operating on these cases in later life I have often observed this stenosis of the canal with the existence of hernia or of fluid—indeed, the communication is so narrow as barely to admit the passing of a probe, but it may become so enlarged as to allow the descent of a considerable amount of intestine or omentum. I believe that in many instances no real obliteration ensues from the wearing of trusses and that patency exists throughout life without hernia. A case bearing this out occurred in the practice of Mr. Stanley in 1859 at St. Bartholomew's Hospital on the removal of a malignant testis from a young man. During the operation the vaginal process was ascertained to be patent, so as easily to allow the passage of the forefinger into the general peritoneal cavity. Prior to the operation the patient had never been the subject of hernia, nor was he even after his discharge from the hospital. This case demonstrates that other factors of hernia exist above a patent canal and an unduly large abdominal ring. One potent factor is the elongated mesentery. It is not an unusual history that hernia takes place suddenly for the first time and of considerable size when patients are in ill-health or recovering from a long illness. The herniæ under these circumstances are large, inasmuch as the sac is of congenital origin and capable of receiving a considerable amount of intestine.

Hernia in this variety of congenital patency easily becomes strangulated and often consists solely of intestine. The prognosis is serious, as the constriction is severe at the inner ring, and often there is no omentum to act as a buffer at the seat of strangulation. Hospital records show conclusively that strangulated congenital hernia entails much greater risks than are entailed in ordinary acquired hernia.

In early infant life, before any curative operation is admissible, the only course to adopt for the treatment consists in the application of some retentive support, and it may be stated that in the large majority of cases the prognosis is good. Whether the canal is permanently closed and becomes converted into a fibrous cord we have no means of knowing, but we often see in later life that the tube is still patent. The presence of fluid in the sac, passing to and fro from the peritoneal cavity, renders the outlook much less satisfactory than if the protrusion is only intestine or omentum. Should this condition exist an operation for the cure should be strongly recommended as soon as practicable and the results of such operations are eminently satisfactory. Two of the reasons strongly urged for the radical cure are the pain and the inconvenience inflicted on these little patients from wearing trusses.

In this and in the funicular form of congenital hernia I have usually observed that the constituents of the chord are more intimately adherent to the sac than in ordinary acquired hernia and the danger to the vas deferens is thus correspondingly increased. The walls of the sac are usually very thin and diaphanous.

In ectopion vesicæ it is very common to find in association with the exstrophy of the bladder both testes retained in the inguinal canal with herniæ into their unclosed sacs. I have seen six cases of this anomaly and all were the subjects of congenital hernia. These were all subjected to operation for the relief of the exstrophy, and on presenting themselves some time afterwards I ascertained that in four of them the testes had descended into the scrotum. In two the hernia still existed, while in the other two the hernia was cured.

Herniæ into the funicular process are often met with but their diagnosis presents greater difficulties than do those of the preceding variety as there are no anatomical conditions on which we can rely. A well-marked example is usually very characteristic; for its elongated sausage shape, its uniform calibre throughout in a line with the axis of the chord, passing down to the upper border of the testis, from which, however, it is separated by a longer or shorter constriction—all proclaim the congenital nature of the extrusion. All, however, do not possess these definite characters.

Birkett has accurately demonstrated the nature of funicular hernia and is of opinion that most of the extrusions occurring in infancy and early life are of this variety. This opinion can only be conjectured, as dissection alone can demonstrate its accuracy; but I have a strong opinion that funicular hernia is more common than is usually believed. The proportion of hernia into the cavity of the tunica vaginalis testis and into the funicular process is represented by one in every 29 cases, or 3½ per cent. of all cases of inguinal hernia.

Though funicular herniæ are not so liable to strangulation and are reduced with greater ease than are those into the cavity of the tunica vaginalis, they are retained by instrumental support with greater uncertainty. The difficulty of retaining funicular hernia by means of trusses is a cogent reason for recommending the operation for the radical cure, and, as in the operation for the first variety of congenital hernia, the results are most satisfactory. The nature of funicular hernia was recognised by Camper, Hunter, and others.[11]

The third variety of congenital hernia is the infantile hernia, which is not so rare as is commonly supposed, for MacEwen, Wright, and other writers have described instances, the first named not fewer than five. I have only operated in a single instance, and the nature of the protrusion was not recognised before operation and this appears to be the experience of others. Attention has already been drawn to this variety in my anatomical description, describing three forms: the first in which the hernia lies behind the chord and the testis; the second in which the hernia bulges the posterior wall of the vaginal cavity forwards; and the third which invaginates from above a sac into the enclosed tunica vaginalis testis. This variety is denied by some authors, but the plate in Astley Cooper's work by Forster appears as an example of this rare form. In the earlier part of my lecture I described at some length and showed the specimen of a young man with an encysted hernia and there are to my mind examples of encysted hernia in other London museums. The appearance of these invaginated sacs bears no likeness to the first and second varieties of infantile hernia, for the walls are thin and fibrous, with no evidence of the plica vascularis, and there is an epithelial lining making the interior of the sac smooth and secerning.

There is yet another example of congenital hernia which strictly should be included in the first variety as the hernia lies in the cavity of the tunica vaginalis testis. As it has, however, characters distinct from this variety it may well be placed in a class of its own, as it is associated with a misplaced, ill-developed testis. This hernia is called "interstitial hernia," and is one of the rarer yet most interesting of the congenital protrusions. It has received many names, as "interstitial," "inter-muscular," "ascending," "intra-parietal," "inter-parietal," "pro-peritoneal," and "hernia en-bissac" by French authors. Many of these appellations are unfortunate, as they fail to convey an accurate description of the relations of the hernia to the abdominal walls, but the least satisfactory is that of "pro-peritoneal," for it gives no clue to the position of the hernia to the abdominal walls. I have therefore retained the term "interstitial" as if not affording much information it is not incorrect as to the structural relations.

Interstitial hernia is primarily situated within the abdominal muscular walls, usually in the patent vaginal process, within which is placed an ill-developed testis. In only two instances were the testes normally developed in the scrotum. I have appended the notes of 42 cases of interstitial hernia in males 35 being on the right side, five on the left, and two on both sides. The positions of the testes vary within large limits, but by far the larger number were retained within the inguinal canal.

TABLE VI.—*Showing the Position of the Testes in Interstitial Hernia.*

Testes.	Right.	Left.	Double.	Total.
In the scrotum	2	—	—	2
High up in the scrotum ...	2	—	—	2
Outside the external abdominal ring	1	2	1	4
In the inguinal canal	26	3	1	30
In Scarpa's triangle ...	1	—	—	1
Not stated	3	—	—	3
	35	5	2	42

This number of interstitial herniæ was recorded out of a total number of nearly 50,000 cases, making the proportion of one case to 1100 cases. This table shows that the testes in two instances were situated high up in the scrotum; in four these organs were placed immediately outside the external ring; in 30 the testes were retained within the canal; one was in the centre of Scarpa's triangle, while in three cases the position of the testes was not recorded. In nearly all the corresponding half of the scrotum was not developed or absent for in 34 cases the scrotum on that side was absent moderately developed in three instances, and fully developed in two patients When the testis lies immediately outside the ring it has been extruded by an advancing hernia and certainly so in the solitary instance in which the testis and hernia were found in Scarpa s triangle The arrest of the testis when outside the external ring is caused by the dense fibrous tissue which prevents any further descent.

---

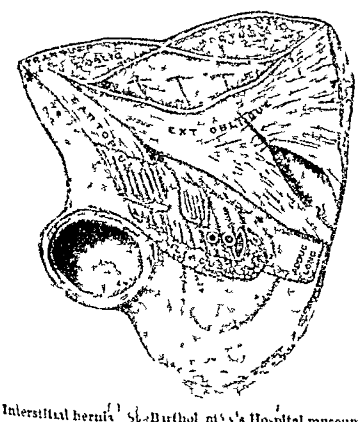
[11] Camper: Icones Herniarum, Tab. x., Fig. 3. Works of Hunter, by Palmer, Plates xxv. and xxvi. W. Lawrence: Treatise on Ruptures, fifth edition, 1838, p. 534. Scarpa: Wishart's translation, Memoir 11, Section 10.

In interstitial hernia there is not infrequently extruded one or more pouches of peritoneal sac through the outer ring If there is only a single pouch the testis lies within the canal and the pouch is occupied by fluid or intestine, but if there are more, then the testis lies in one of them In 75 per cent the testis remains in its original position in the canal, where it usually attains a higher degree of development than when extruded through the outer ring. Its retention in this original position is most likely due to its large size, which prevents its extrusion If the testis is situated high up in the canal and in the posterior part of the sac it remains in this position, but when it is placed lower down it is often pushed through the ring If retained within the canal the testis is less tender than if placed outside the canal

Herniæ of the interstitial form are usually confined to the dilated inguinal canal, but if they do pass beyond it it is only for a short distance, and some cases have been described in which the hernial sac has passed into the scrotum, leaving the testis still in the canal Occasionally the external ring is split up for an inch or more, in which case both testis and hernia are extruded through the gap in the external oblique aponeurosis The corresponding half of the scrotum is mostly ill developed or absent The protrusion as it enlarges cannot emerge through the outer ring in consequence of the denseness of the fascia, and thus it expands the canal in the direction of least resistance, so that the sac may present two or more dilatations

Interstitial herniæ are classified according to the direction which the protrusion takes after its passage through the inner ring 1 The hernia may ascend and separate the aponeurosis of the external oblique from the muscular internal oblique This is the most common variety and is called the "interparietal" or "intermuscular form 2 The hernia may split the aponeurosis of the external oblique from the outer ring to a variable distance or it may pass through the external ring and take various directions The hernia thus lies in front of the aponeurosis of the external oblique, between it and the deep fascia This is the preparietal or pre aponeurotic variety 3 The hernia may pass between the abdominal peritoneum and the fascia transversalis lying in the subperitoneal fascia, whence it may extend in different directions This is the post parietal or post muscular variety

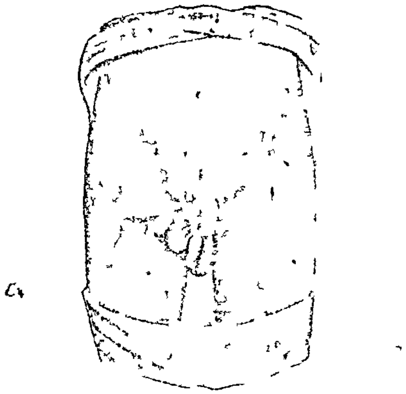
FIG 6



Interstitial hernia St Bartholomew's Hospital museum Specimen 2157a

The directions into which this form of hernia may extend are (*a*) downwards and backwards towards the iliac fossa, where it rests on the iliac fascia—hernia inguinalis supra iliaca; (*b*) downwards and inwards towards the horizontal ramus of the os pubis, where it lies in front of the bladder—hernia inguinalis ante vesicalis, and (*c*) virtually upwards for some distance towards the umbilicus—hernia inguinalis ascendens 4 The hernia may protrude to a limited extent beyond the outer ring with or without the testis and then pass into the scrotal, inguino-scrotal, or crural regions To these varieties the names "scrotal," "inguino scrotal," and "crural" interstitial hernia have been given

FIG 7



Interstitial hernia two accessory pouches, the upper pouch containing intestine the lower containing the testis

Interstitial hernia may be discovered for the first time at any age although the conditions necessary for its existence must have been congenital There can be little doubt that this protrusion has occurred years prior to its discovery, so that the statements by the patients are not to be relied upon Of the 42 cases of interstitial hernia I find that in nearly 45 per cent the age at the first discovery of the hernia was under one year, 16 per cent between one year and 20 years, 29 per cent occurred between 21 and 40 years of age, 5 per cent between 41 and 60 years, and 5 per cent between the ages of 61 and 80 years

TABLE VII —*Showing the Age at the First Discovery of Interstitial Hernia*

Age period	Cases
Under 1 year of age	19
Between 1 year and 20 years	7
Between 21 and 40 years	12
Between 41 and 60 years	2
Between 61 and 80 years	2
Total	42

The frequency of the occurrence of interstitial hernia in the earlier periods of life affords proof of some congenital defect in the position of the testes and probably also in the later years of life, as in nearly all the cases the testes were ill developed in the inguinal canal Interstitial hernia cannot be considered common in comparison with the total number of ruptured males seeing that out of 49 390 patients from January, 1889 to November, 1900 only 42 were the subjects of interstitial hernia, or one in 1175 cases

Incidentally I may draw attention to the comparative frequency of interstitial or quasi interstitial hernia in women, for these herniæ present many differences from those prevailing in men Our records show that 18 cases occurred out of 13 583 female patients so that the proportion is one in 760 patients, or nearly twice as frequent as in males These herniæ in women are often of great size, and in one patient, 47 years of age, the protrusion—preparietal—extended as high as the right costal margin above to the linea alba on its inner side, and overhung the thigh for a considerable distance. It measured 11 inches in its transverse and seven inches in its vertical diameter and was irreducible. In one patient an oval, hard body was felt in the upper part of the sac after reduction of the enterocele, of the size and shape of an ovary. Of the 18 cases, two only were noticed at birth, eight between the ages of 21 and 40 years, four between 41 and 60 years of age, and three between 60 and 70 years of age, while in one patient the first occurrence of the hernia was doubtful.

The causes of interstitial hernia in women are probably due to distension of the abdominal muscles during pregnancy, for most of them were mothers of large families.

The treatment of interstitial hernia in males is neither scientific nor satisfactory, for the pressure of a truss is mainly directed to covering the hernia and in most instances is unable to effect complete retention. As a rule, the deviated testes accommodate themselves under the truss without much inconvenience to the patient if the truss is properly adjusted. The testis may safely be left to take care of itself. Operative measures for the reduction and cure of the hernia are often attended with difficulty, as the separation of such an extent of the abdominal muscles renders the complete approximation of the parietes almost impracticable. The size of the hernia is so great that the abdominal cavity *is unable to receive such a large accession of viscera,* so that the question of an enterectomy must be considered to allow of the complete reduction of the extruded mass.

THE CAUSATION, PREVENTION, AND TREATMENT OF POST-PARTUM HÆMORRHAGE.[1]

BY G. F. BLACKER, M.D., B.S. LOND., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN TO OUT-PATIENTS AT UNIVERSITY COLLEGE HOSPITAL; OBSTETRIC PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

THE subject of our discussion this evening must always be one of great interest to medical practitioners. The appalling suddenness of the accident and the great risk to life entailed upon the patient render it a matter for congratulation that cases of post-partum hæmorrhage are not met with more frequently and that its occurrence can usually be avoided by proper prophylactic treatment.

In the University College Hospital maternity department during the period from August 1st, 1893, to Dec. 1st, 1900, 15,130 women have been delivered. Of this number 139, or one in 108, have suffered from some degree of post-partum hæmorrhage. In 100 of these cases, or one in 151, the amount of blood lost was not very excessive and did not cause any marked symptoms; in 31 of the cases, or one in 488, the loss was considerable and was accompanied by marked symptoms; while in eight instances, or one in 1881, the *patient's life was endangered,* two of these cases ending fatally—a mortality of one death in 7565 deliveries. Amongst 20,378 confinements in the Charité Hospital in Berlin only two deaths occurred from post-partum hæmorrhage—a mortality of one in 10,189. Veit,[2] who has collected a large number of statistics in addition to these, found amongst 47,065 labours only five deaths from atonic post-partum hæmorrhage—a proportion of one in 9413 confinements. Although the *death-rate from* post partum hæmorrhage is therefore relatively small, yet the total number of fatal cases must be considerable. Dührssen[3] states that 300 women die annually in Prussia from this cause, while the frequency of cases causing severe symptoms—viz., one in every 488 confinements in the University College Hospital maternity department—renders this accident of labour one of much importance.

I propose to discuss post-partum hæmorrhage under the three headings of Causation, Prevention, and Treatment, and to confine my remarks to the variety due to atony of the uterus.

Before passing on to consider its causation I may just remind you of a few facts concerning the mechanism of the third stage of labour. The anatomical studies of Barbour,[4] Pinard, and Varnier[5] have demonstrated that at the end of the second stage of labour the placenta is still completely attached to the uterine wall. Separation of the placenta begins with the third stage of labour and is due to the contraction and retraction of the uterine muscle. It is this latter property of active retraction—or what may be termed the tonicity—of the muscle which prevents the occurrence of hæmorrhage when the utero-placental vessels are torn through during the separation of the placenta. The absence or inhibition of this power of retraction is the chief cause of post-partum hæmorrhage, giving rise as it does to atony of the uterus or inertia uteri. It is because the retraction of the uterine muscle is prevented by the presence of the fœtus in utero that premature separation of the placenta is so often accompanied by severe hæmorrhage.

CAUSATION.

The causes of post-partum hæmorrhage are, therefore, to be sought in the conditions giving rise to uterine inertia. These may, for convenience of discussion, be classified as follows:—

1. Feebleness, exhaustion, or malnutrition of the patient. This may be due to the condition of chronic starvation so common amongst the London poor, or to the occurrence of ante partum hæmorrhage, or it may be the result of some disease complicating the labour, such as grave heart disease.[6] The great danger of even a slight degree of post-partum hæmorrhage in cases of severe ante partum hæmorrhage is well known. Ord[7] has shown that labour complicated by myxœdema is very likely to be followed by hæmorrhage. Albuminuria is often asserted to favour the occurrence of post-partum hæmorrhage. This is not borne out by our experience, and its influence in causing this complication of labour is denied by Pinard.

2. Over-distension of the uterus and undue stretching of the uterine muscle such as occurs in cases of hydramnios or multiple pregnancies. Unstriped muscle if stimulated to contract passes into a condition of exhaustion more rapidly when stretched by means of a weight than when it is not so stretched.

3. Exhaustion of the uterine muscle from frequent child-bearing and prolonged labour. One of the commonest causes of post-partum hæmorrhage is the application of forceps and the delivery of the child when pains are absent and the uterus is exhausted and in a condition of secondary uterine inertia—the so called "temporary passiveness" of Braxton Hicks.[8]

4. Pathological conditions of the uterine wall. The presence of fibroid tumours is especially liable to cause post-partum bleeding if the placenta be attached over the site of the tumour. Marked fatty degeneration of the uterine muscle has been described by Bossi[9] in three cases of pregnancy, and he thinks that this may possibly be a cause of inertia in some instances. Fritsch[10] has called attention to cases of uterine atony due to septic infection occurring during labour, the paralysis of the uterine muscle being analogous to that of the intestinal muscle seen so commonly in cases of septicæmia.

5. Some mechanical hindrance to the contraction and retraction of the uterus, such as the retention of the placenta in utero or the presence of adhesions between the uterus and surrounding structures. Graily Hewitt[11] described a fatal case apparently due to this latter cause, and in 102 cases of labour following the operation of ventro-fixation of the uterus Negri[12] found five cases of severe post-partum hæmorrhage due to the adhesions present—a proportion of one in 20, much above the average.

6. Too rapid emptying of the uterus, either by the application of forceps or after version. If the child be rapidly extracted after version in cases of placenta prævia with a rigid cervix tears extending through the placental site in the lower uterine segment are very likely to occur and dangerous hæmorrhage to ensue.

7. Extreme nervous depression and shock such as may

follow the birth of a dead child may account for uterine atony in some cases. That such a mental condition should cause hæmorrhage is not surprising when we remember how frequently irregular cardiac action and vaso-dilatation are produced by various emotions.

8. The administration of chloroform has often been regarded as a cause of uterine inertia. That chloroform gives rise to post-partum hæmorrhage is probably not true, but that its administration has some effect upon the pains is easy to determine clinically and is proved by the observations of Pinard[13] and Westermark.[14] The last-named observer finds that chloroform when given to the obstetrical degree lengthens the intervals between the pains, diminishes the frequency of the pains, and causes the individual contractions to begin more suddenly and pass off more rapidly. When given to the surgical degree it produces the same results but to a more marked extent. Pinard found that *chloroform prolonged the intervals between the pains*, while it diminished the severity and power of the pains, and he concluded that it affected the power of retraction of the uterine muscle rather than its power of contraction.

9. Another possible cause of excessive bleeding after delivery is deficient coagulability of the blood. Such a condition occurs in cases of septic infection and hæmophilia. The latter disease is possibly more often suspected than actually met with, but the cases recorded by Kehrer[15] show how dangerous a complication of pregnancy and labour it may be.

PREVENTION.

In discussing the preventive treatment of post-partum hæmorrhage it is necessary to consider the treatment of the patient during pregnancy and during labour. It is important that all patients should enter upon labour in as favourable a condition of health as possible. Attention must therefore be paid to the general health in all cases where this may be necessary. If the patient has lost excessively at her previous confinements small doses of ergot and strychnine combined with iron or hydrochloric acid may be given during the last month or so of pregnancy, as recommended by Dr. Lombe Atthill.[16] Women with a history of hæmophilia should be given[17] calcium chloride in 10 grain doses three or four times a day for the last two or three weeks preceding delivery. Although, as we have seen, it is very doubtful whether albuminuria *per se* is a cause of post-partum flooding, yet for obvious reasons it must be treated and the patient should be placed upon a strict milk diet. The great value and importance of preventive treatment is well exemplified by Spiegelberg's statement. He writes: "I certainly do not exaggerate when I say that severe post-partum hæmorrhage is almost without exception the fault of the attendant."[18]

In no less than 50 of the 139 cases occurring in the University College Hospital maternity department the child was born before any assistance arrived. In six out of the eight severe cases this happened, including the two cases in which the women died. It is, unfortunately, a common practice amongst the patients in this department to postpone sending for assistance until as late as possible so as to avoid the necessity of being examined. How dangerous a custom this is the facts I have mentioned show, and in all probability one of the two women who died lost her life as a result of this practice. The details of these two cases are shortly as follows.

CASE 1.—A woman sent up to the hospital for attendance at 9 P.M. on August 3rd, 1895. When she was seen slight pains were occurring every half hour. The membranes were unruptured and the internal os was of the size of a sixpenny piece. The pulse was normal. The patient was anæmic and feeble. At 10.30 P.M., as the conditions of the cervix had remained the same, she was left and instructions were given to send up again when the pains became more frequent. Between 4 and 5 A.M. on August 4th the husband came up to the hospital and said that the child was born. On the arrival of the student in attendance the patient was found to be dead. The bed was soaked with blood. The child was born and was alive; the placenta was retained partly in the uterus and partly in the vagina. The uterus was enormously distended and contained large quantities of blood and blood-clot. The pains had continued very feeble until just before the end, when with three or four very strong pains the child was born. The sister of the patient was the only person present at the time. All attempts at resuscitation completely failed.

CASE 2.—*A woman sent up to the hospital on August 28th*, 1897, two and a half hours after the birth of her child, for assistance on account of severe flooding. On the arrival of the medical attendant the patient was found to be cold, extremely blanched, pulseless, and speechless. The placenta, retained and only partially separated, was removed by the hand. There had been very severe post-partum hæmorrhage which had, however, ceased. The patient was given hypodermic injections of ether and three pints of water and two ounces of brandy were injected into the rectum. She rallied a little but died just after intravenous transfusion had been commenced.

The prevention of post-partum hæmorrhage is of even greater importance than its treatment, and it may with truth be said that the skill of an accoucheur can be estimated by the number of such cases that occur in his practice. During labour it is often good treatment to rupture the membranes, even before the cervix is fully dilated, in cases where we fear the occurrence of hæmorrhage after delivery. During the second stage of labour care must be taken not to allow the uterus to become exhausted and to recognise as early as possible conditions likely to cause obstructed labour. When the uterus is in a condition of secondary inertia the mistake of delivering with forceps must be avoided and the case treated by opium and rest, while in cases of obstructed labour the necessary measures must be at once adopted to overcome the obstruction. When towards the end of the second stage the pains are feeble and no progress is being made ergot in doses of from half a drachm to one drachm of the liquor ergotæ ammoniatus may be given, if it is perfectly certain that the labour is an absolutely normal one. The practice of giving ergot before the birth of the child *is undoubtedly in certain cases* a very valuable one and it is regarded at the present time with more disfavour than it deserves. This method is especially applicable in cases where deep anæsthesia is necessary in order to complete delivery.

It is, however, in the proper management of the third stage of labour that the secret of preventing post-partum hæmorrhage lies. Too often it occurs as a sequel of hasty and premature attempts to express the placenta, with the result that a portion of the placenta or membranes is left in utero. A sufficient amount of time must be allowed to elapse to permit of proper separation of the placenta, and under ordinary circumstances no attempt should be made to express it until *from 20 to 30 minutes after the completion of* the second stage of labour. From the time the child is born until the placenta is expelled one hand should be kept continuously upon the uterus. The dorsal position has many advantages during the third stage of labour, but in cases where bleeding occurs the necessary manipulations are most readily carried out with the patient on her side.

At the end of the second stage the fundus of the contracted uterus is usually at the level of the umbilicus. Towards the end of the third stage it will be found to have ascended until it lies from one and a half to two inches above the umbilicus.[19] This indicates that the placenta has been separated and expelled from the upper uterine segment into the lower uterine segment and that it is in a condition in which it can be easily expressed.

It is more particularly in cases where it is necessary to revive an asphyxiated child, or where the medical attendant's attention is directed away from the mother, that severe post-partum hæmorrhage is likely to occur. It is impossible for a uterus to relax completely unperceived if it be watched with the hand during the whole of the third stage of labour. In any case where hæmorrhage has occurred or where the uterus shows a tendency to again relax it must be carefully supervised until it is certain that contraction and retraction are complete and permanent.

TREATMENT.

When post-partum hæmorrhage does occur the medical man must have a plan of treatment ready and be able to carry it out rapidly and efficiently. Personally, I do not consider that I am doing justice to my patient or to myself unless I have ready at hand the few appliances necessary to enable me to deal with such a complication should it arise.

The best method of treating a case of severe hæmorrhage will depend upon whether the placenta is still in utero or not. The ordinary treatment may be outlined as follows. If the placenta be retained it must be at once expressed, or if this is found impossible removed by the hand. A hypodermic injection of ergotin if ready may be given and the uterus kneaded through the abdominal wall while the nurse is ordered to prepare a hot douche. If the hæmorrhage be profuse and the uterus does not respond to the kneading bimanual compression may be carried out until the douche is ready. In the small number of cases where the hot douche fails to excite any uterine contractions and the tone of the muscle is entirely lost recourse must be had to continued bimanual compression, to plugging the uterus with gauze, or to the application of some styptic, such as perchloride of iron, to produce clotting of the blood in the vessels.

[19] Varnier: La Pratique des Accouchements, p. 259.

We may now consider these various methods of treatment rather more in detail.

It is impossible for the uterus to contract and retract while the placenta is still in utero, and therefore its removal must be undertaken before any attempts are made to excite uterine contractions. Whenever possible this should be effected without the introduction of the hand into the uterus. No time, however, must be lost if expression fails, and when necessary the hand must be passed into the uterus and the placenta and all blood-clot removed. The introduction of the hand has the advantage that it is a powerful excitant of uterine action. Ergot takes too long a time to act to be of much value in the treatment of a case of severe bleeding. In all cases where it is ready a hypodermic injection of ergotin may be given so that the assistance of its action may be obtained in rendering permanent the uterine contraction and retraction procured by other more speedy methods of treatment. In the less severe cases kneading the uterus is often all that is required to excite contractions and to arrest the bleeding. In the more severe cases this is not sufficient and in these a hot douche must be given.

There are several important details to be observed in employing this form of treatment. The water must be used in large quantities and at a temperature of not less than from 117° to 120°F. The uterine tube should be carried into the uterus up to the fundus and the whole of the inner surface of the organ irrigated by the fluid. This is rendered more easy and at the same time the hæmorrhage may be to some extent checked if the uterus be drawn down to the vulva with a vulsellum. This method of drawing down the uterus is at times alone sufficient to arrest the bleeding no doubt by the kinking and compression of the uterine arteries which it causes.[20] Some antiseptic may be used in the water, such as creoline or iodine, but plain hot water will do perfectly well in an urgent case.

Bimanual compression of the uterus is the best method to employ when the hot douche is not immediately available or where it fails to excite uterine contractions. The uterus seized by the hand on the abdomen is compressed against the anterior abdominal wall, the posterior surface of the symphysis pubis, and the other hand placed in the anterior vaginal fornix. The pressure should be exerted as far as possible upon the placental site; no great force is required and it can be continued for a considerable length of time, although at the cost of a good deal of fatigue on the part of the attendant. The chief objection to this method is the difficulty sometimes experienced in grasping the completely relaxed uterus between the two hands. Whether the fist or the extended hand be introduced into the vagina is a matter of indifference so long as the anterior and posterior walls of the uterus are kept firmly in contact. All the 139 cases of hæmorrhage occurring in the University College Hospital maternity department were treated by the hot douche or bimanual compression. In no case near full term was the uterus plugged with gauze or injected with styptics.

As a routine means of treatment plugging the uterus is certainly inferior to bimanual compression. There are, however, two classes of cases in which the latter method is specially indicated—viz., where the uterus is prevented from contracting and retracting by the presence of adhesions or by the existence of fibroid tumours in its wall. Schauta[21] has suggested that in some severe cases of hæmorrhage the uterine vessels are atheromatous, and in any instance where this condition is suspected gauze-plugging would no doubt be the best treatment. Schmit[22] has recorded a case of this kind in which the patient died from uncontrollable hæmorrhage, although the uterus after plugging had failed was ultimately removed in an endeavour to arrest the bleeding. On microscopic examination well-marked hyaline degeneration of the vessels at the placental site was found. Plugging the uterus may be carried out in the following way. The uterus is drawn down to the vulva with a vulsellum—a manœuvre which has the advantage of assisting to arrest the hæmorrhage—or is pushed down by pressure through the abdomen. The left hand is introduced up to the fundus and all blood-clot removed. The strips of gauze or of any other available material wrung out of an antiseptic lotion are passed into the uterus under cover of the fingers of the left hand by means of a pair of uterine dressing-forceps or the intra-uterine douche tube, and the cavity firmly and completely packed from above down. Special care must be taken that no space in which blood could accumulate is left between the fundus and the gauze. In bad cases the vagina should also be plugged. A large pad of wool may then be placed over the vulva and a binder and T bandage applied with considerable pressure. The plug is taken out at the end of from 18 to 24 hours. If hæmorrhage continues the plug must be removed, the uterus washed out, and then replugged.

Since 1893 there has not been any case of post-partum hæmorrhage alone in the maternity department of University College Hospital in which plugging the uterus has been required. This method has, however, been frequently employed for hæmorrhage after abortions and other conditions and is of great value in the treatment of some cases of rupture of the uterus.[23]

The last mode of treatment I have to mention is the application of powerful styptics to the interior of the uterus, a method which at the present day is almost superseded by gauze-plugging. The drug most commonly used is the liquor ferri perchloridi fortior of the strength of one part to three parts of water.[24] It may be injected into the uterus by means of a tube, or the interior of the organ may be washed out with a sponge or wool dipped in the solution. It is undoubtedly a most efficient means of producing thrombosis, but its dangers outweigh its advantages. It is extremely likely to produce sloughing, septic thrombosis, and general septic infection. Turpentine and vinegar may also be employed in the same way.

In cases where the hæmorrhage has been successfully arrested but where the loss has been excessive the condition of the patient is usually very grave, and energetic after-treatment is required if her life is to be saved. The greatest reliance is to be placed in the treatment of such cases on the hypodermic injection of strychnine, ether, and digitalin. Ether may be injected in doses of 10 minims every 10 or 15 minutes until five or six doses have been given. Where cardiac failure is very marked hot water or normal saline solution should be injected. The former may be given by the rectum, the latter may be injected under the skin or into a vein. In severe hæmorrhage the most valuable of these methods is venous transfusion. Infusion of hot water or saline fluid has been carried out in 10 of our cases—five times by the rectum, four times into a vein, and once into the sub mammary connective tissue. The amount of fluid employed varied from one to five and a half pints. One patient was transfused twice, three pints being introduced into one arm and two and a half pints into the other.

Rectal injections of hot water with or without brandy are of great value in cases where the circulation is not too feeble. They act as a powerful stimulant and in such cases the fluid is no doubt absorbed. In cases of severe hæmorrhage accompanied by a very feeble action of the heart it is quite certain that no absorption occurs either from the stomach or bowel. In such cases venous transfusion must be carried out and gives exceedingly good results. My experience of subcutaneous transfusion in cases of septic infection and other conditions leads me to regard it as too slow a method to use in cases of hæmorrhage. Common salt can be obtained in any household, but it is best to carry it as chemically pure sodium chloride or as a concentrated solution in a sealed glass tube. The solution employed should contain one drachm of salt to the pint, and must have a temperature of from 101° to 102° F. It will cool down to blood heat while passing through the transfusion apparatus. Care should be taken to see that the temperature is maintained during the operation, and this can most easily be done if the solution be prepared in small quantities at a time. It should in all cases be filtered through muslin before use. If it be necessary to repeat the transfusion another vein must be opened. When the patient has been revived and the immediate danger of death from syncope is staved off the extreme restlessness and headache that so frequently follow may be treated by large doses of opium or morphia. Any further tendency to syncope is best treated by raising the foot of the bed and the administration of liquid food and stimulants in small quantities at frequent intervals. The great risk of subsequent sepsis must not be forgotten and the convalescence of such patients is of necessity a slow process

BY WILLIAM MACKIE, M.A., M.D. ABERD.,
VISITING PHYSICIAN AND SURGEON, DR. GRAY'S HOSPITAL, ELGIN.

MANY years ago Sonstadt came to the conclusion that the minute quantity of iodine contained in sea-water is present in the form of calcium iodate.[1] To this substance, existing, as he calculated, in the proportion of one part in about 250,000[2] parts of sea-water, he attributed "not only the salubrity of the sea, but, through the medium of the atmosphere, of the land also." At a somewhat later date the same chemist made "experiments on the properties of iodate of calcium as an antiseptic and disinfecting agent"[3] Some of these experiments I have repeated, with this difference—that where Sonstadt mostly used the dry powder I have used a saturated solution of the salt, but the results obtained by me have in every instance been in complete accord with those obtained by him.

About 15 months ago I began tentatively to use calcium iodate in surgical practice as an antiseptic dressing in place of iodoform. For about the same time I have been using it, though to a less extent, in medical practice also. The results in both cases have led me to conclude that calcium iodate is a substance likely to prove of very considerable value both for external and internal use. Up to the present, however, my observations have been more particularly directed to its surgical applications. For the last six months or more I have used it without hesitation in all kinds of surgical work where iodoform is usually indicated and, I may say, to the almost total exclusion of the latter substance, and my belief in its efficacy has only increased with its continued use.

The theory of the action of calcium iodate as an antiseptic is not far to seek. It is an iodine compound containing 51 per cent. of iodine and in addition 16 per cent. of available oxygen. On contact with putrescible organic matter, whether in acid or in alkaline medium, like other iodates it slowly liberates iodine. In alkaline solution, while the organic matter is being oxidised by the oxygen set free from the decomposing iodate, the iodine by a reaction well known to occur in alkaline media slowly re-forms iodate through the decomposition of water. The iodate so re-formed in contact with another portion of putrescible matter yields further proportions of free oxygen and iodine to act as before, and so on. The process, therefore, is, so to speak, a continuous one As most pathological discharges are alkaline we have present in such cases the necessary conditions of the continuous action of an iodate. In an acid medium, also, in the presence of reducing substances such as easily oxidisable organic matter, iodine is liberated and by the decomposition of water it sets free oxygen which is used up in oxidising any unstable organic compound that may be present. The iodine in this case passes into hydriodic acid or an iodide and so eventually ceases to act. If, however, the acid present in a medium be hydrochloric—as, for example, in the gastric juice—chlorine, though not the only substance liberated, is certainly the one liberated in greatest abundance. Chemical equation shows that calcium iodate in contact with hydrochloric acid liberates as nearly as may be four-sevenths of its weight of chlorine On this fact theoretically depends its use as a gastro-intestinal antiseptic. As regards antiseptic action something no doubt depends on the chemical instability of iodates generally and of this iodate in particular, on the nascent action of the liberated products, and in this case on the fact that the base forms insoluble compounds such as carbonate and phosphate in contact with alkaline discharges, thus probably facilitating the free operation of the acid radicle of the salt, on which of course its particular virtue really depends

From this view of its action it is to be inferred that calcium iodate acts more as a destroyer of the products of bacterial life than as a bactericide of any very decided degree of potency. Of its inhibitory power on bacterial growth there cannot however, I think, be any doubt. It would thus closely conform to iodoform in its action. Further, the function of the salt as a deodorant, of which I have time and again had ample proof, can be easily understood as the result of its chemical action. Iodates decompose sulphuretted hydrogen, precipitating it in part as sulphur, in part oxidising it into sulphuric acid. As the fœtor of foul discharges is no doubt in many cases due to volatile sulphur compounds, if not actually to sulphuretted hydrogen itself, we naturally expect a similar action in their case.

To pass to the practical side, the substance itself is most easily prepared—in fact, it can be prepared by any dispensing chemist as follows: Prepare an aqueous solution of iodine[4] in potassium iodide. Dilute the same till it just transmits light through a depth of three inches. Stir up some bleaching powder with water and filter into iodine solution, with occasional stirring After a time a crystalline precipitate makes its appearance If it is not perfectly white, but some shade of brown or slate-grey, add more iodide of potassium and stir. Run in the bleaching solution to complete decolourisation of the iodine solution. Before collecting the precipitate add a small quantity of very dilute hydrochloric acid to dissolve any carbonate of lime that may have formed during the process Collect on filter, wash once or twice with cold water, and dry on blotting paper or in an oven at a temperature not much exceeding 100° C The product is $Ca(IO_3)_2 + 6\,H_2O$. The particular point to be attended to is to keep the iodide of potassium in excess during the precipitation. Part of the iodide is itself oxidised to an iodate and by double decomposition with the chloride of calcium present in the bleaching solution falls as iodate of calcium. By this particular action on an iodide in alkaline solution the quantity of iodide of potassium is gradually reduced and may thus in time become insufficient to keep all the iodine in solution. From this secondary reaction the yield of calcium iodate is always in excess of what might be expected from the simple oxidation of the quantity of iodine taken.

Iodate of calcium is without taste or smell, though a slight iodine odour may be detected on opening a bottle in which it has been kept for some time. At 11 5° C. I found its solubility to be about one in 380 parts of water. In solutions of even this dilution, however, it shows a wonderful degree of potency in inhibiting decomposition, in preserving food substances, and in checking fœtor, as the following examples will show (Examples 1 and 3 are practically repetitions of experiments by Sonstadt).

1. On March 21st, 1899, about two drachms of freshly passed urine were placed in an unsterilised test-tube and an equal quantity of a saturated solution of calcium iodate added to it. The mixture would thus contain about one part of iodate in 800 parts of the solution. A control was made in a similar test-tube by adding to the same quantity of urine its own bulk of distilled water. Both tubes were freely exposed to the air. At the end of a week the control stank abominably, while the tube containing the iodate was perfectly fresh and exhaled a somewhat aromatic odour which could not in any way be associated with urine. It continued to exhale the same pleasant odour and appeared perfectly sweet and clear up to June 26th when the experiment was brought to an end by an accident to the tube. A similar experiment by Sonstadt, where, however, the dry salt had been added to the urine, would indicate the possibility of its potency extending over a much longer interval. Another experiment

[3] Ibid, vol. xxviii, p 297.

[4] The iodine is not necessary. A solution of potassium iodide may be used alone, the iodine being set free by the bleaching solution and dissolving in the excess of iodide.

went to show that even in the proportion of about 1 in 7000 parts the decomposition of urine was markedly delayed by calcium iodate.

2. One and a half ounces of milk taken directly from the house supply had one and a half grains of iodate added to it. It was then allowed to stand freely exposed to the air for five days. At the end of this time it was found to be perfectly sweet and palatable and was drunk with impunity.

3. A piece of meat was suspended in a saturated solution of the salt and was found perfectly fresh at the end of a fortnight.

4 Half an ounce of exceedingly fœtid pus from an empyema which had burst through the diaphragm and was burrowing between the anterior abdominal wall and its peritoneal lining was shaken up with a few grains of the dry salt. In ten minutes the foul odour was all but discharged though only a small portion of the salt had evidently dissolved. An hour later the pus to which the iodate had been added was filtered in the open laboratory without its presence being indicated by any objectionable exhalation.

The result of these experiments certainly gave promise of the substance being of use in surgical work and actual trial has in my hands amply confirmed the anticipation. The following cases, which are necessarily somewhat briefly described, are to be looked on as types of the several classes of cases in which calcium iodate has been used with success rather than as isolated individual cases where it was tentatively employed. A summary embodying the general results in the several classes is appended in each case.

CASE 1.—A man, aged 45 years, was admitted into hospital with old cavities of his right apex, a systolic apical murmur, rheumatic pains in his joints, and slight continuous fever. On the day after his admission his breath was observed to be very fœtid. A saturated solution of calcium iodate was ordered as a mouth wash. Next day, after a couple of washings, his breath was found to be quite sweet and it remained so with only occasional use of the solution during the two months that he was in the hospital. In many other cases of fœtid breath, no matter what the cause, the solution has been used with a like result In alveolar abscess, in carious teeth, in suppurative or follicular tonsillitis, and even in diphtheria, it has been found to inhibit the accompanying fœtor. In more than one case of follicular tonsillitis I have seen it exert a beneficial effect on the primary disease, while in all septic conditions of the mouth cavity I have found its use invaluable. Its absolute tastelessness is a recommendation when so used. The dry powder mixed with a due proportion of prepared chalk or other suitable diluent is suggested as a convenient antiseptic dentifrice.

CASE 2.—A woman, aged 28 years, was admitted into the hospital with a poisoned wound of the leg resulting from a kick over the tuberosity of the tibia. The leg was red, swollen, and œdematous from the ankle to some distance above the wound. The wound was washed out with the saturated solution, and ointment of vaseline (five grains to the ounce) applied on lint was used as a dressing. Next day the redness round the wound had contracted to an areola of the size of half-a-crown, and healing thereafter took place as in a simple wound. The same patient had sores, evidently specific in character, about the size of a florin, on one wrist and on the side of her neck. To these the same dressing was applied with the result that they were quite healed when she left hospital on the ninth day. Many cases of poisoned wound have been similarly treated, with this difference, that latterly I have freely powdered the wound with the dry salt after washing with the saturated solution. In every case this treatment has been perfectly successful.

CASE 3.—This patient was a woman, aged 45 years, who exhibited caries in the lower third of the femur with numerous healed sinuses, as well as discharging sinuses, some of the latter reaching to near the ankle. A huge one opened just to the inside of the patella and looked very foul and angry. The leg generally was very much swollen, red, and tender in parts from the seat of the disease downward. As no operation for the erasion of the carious focus was allowed the sinuses were syringed out daily with saturated solution and their openings were dressed with ointment containing 10 grains to the ounce applied on lint. By the fifth day the discharge of pus from the sinuses had practically ceased and all signs of inflammation had vanished. The patient left the hospital on the eighteenth day temporarily, at least, much improved. In several cases after erasion of carious bone, particularly where it was necessary to leave some extent of surface to heal by granulation, I have found the dry powder an excellent dressing. No hyper-granulation is observed after its prolonged use The astringent character of the carbonate and phosphate of lime resulting from the decomposition of calcium iodate on the wound surface is probably largely responsible for this result. In this respect a striking difference obtains between it and iodoform.

CASE 4.—A man, aged 60 years, was admitted with deep ulcers on the front of each leg. In the case of the right leg the ulcer was of about the size of a crown piece. On the morning of admission a vein from which he had lost a considerable quantity of blood had burst at the edge of this ulcer and led to his being sent into hospital. Nearly a square inch of the periosteum of the tibia was visible at the bottom of this ulcer. On the left leg the ulcer was somewhat larger in superficial extent but not quite so deep. Both were surrounded by unhealthy dark eczematous skin, much of it evidently the scar tissue of previous ulcers from which he said he had suffered off and on for 20 years. The ulcerated surfaces were washed daily with saturated solution and dressed with ointment on lint (five grains to the ounce). After a few days of this treatment healthy granulations had sprung up over both ulcers and the discharge from their surfaces was almost *nil* The patient left the hospital four weeks to the day from the date of his admission with both ulcers practically healed. When seen as an out-patient a week later the skin was continuous over both. No skin-grafting of any kind was done to assist the healing process. A considerable number of ulcers of the leg have been similarly treated, the ointment being mostly, however, 10 grains to the ounce; indeed, the very first case in which calcium iodate was used was a large serpiginous ulcer of the leg in a private patient To this ulcer *lotio nigra* had been applied from time to time with somewhat indifferent success, but after the application of the iodate (10 grains to the ounce) it healed perfectly in three weeks. Another female patient who had suffered from time to time with large and somewhat intractable ulcers of the leg was so pleased with the result in her own case that she had boxes of the ointment made up by a local chemist and presented to some of her friends who were similarly affected.

CASE 5.—In a case of otorrhœa of two years' standing in a child, aged four years, the ear was syringed out with a warm saturated solution and was afterwards insufflated with a powder composed of iodate of calcium and carbonate of bismuth in proportion of one to nine The discharge, which was very fœtid, ceased on the fifth day of treatment, but recurred some time after the cessation of the treatment. In an adult case the fœtor of the discharge was inhibited and the quantity was very much diminished by similar treatment for a fortnight. Latterly, in such cases, I have insufflated the pure powder with correspondingly more successful results.

CASE 6.—A young woman, aged 21 years, presented herself as an out-patient with a sinus on the side of the neck. A tuberculous gland had been excised in a hospital at Edinburgh and she simply came to us for dressing. After ten days' treatment on the lines indicated without improvement she was admitted into the hospital and under chloroform the upper part of the sinus was laid open and curetted. It was found to extend deeply in an upward direction from the opening for one and a half inches and downward and inward behind the sterno-mastoid for two and a half inches. Only the upper one and a half inches were curetted. The raw surface was dusted freely with calcium iodate and allowed to granulate. This it did slowly but effectively and at the end of two months it had entirely healed, a narrow linear scar not distinguishable from that left by a simple incision marking the site of operation. This case is interesting as the first in which pure iodate was applied directly to an operation wound. The first application to a raw surface—as seen at the first dressing—leaves a very fine white adhesive scum, probably consisting largely of carbonate and phosphate of lime, over the incised surfaces. This disappears in a day or two and healthy granulations take its place. It is also interesting to note that in none of the tuberculous cases so treated have any of the livid granulations so characteristic of such cases been at any time seen.

In a few cases it has seemed to me that the saturated solution shows a particular tendency to check pus formation.

CASE 7.—A woman, aged 35 years, had intercurrently with a medical ailment a deep abscess of the axilla. On opening it continued to discharge for some days very offensive pus. After two washings out with iodate solution the fœtor was completely discharged. The formation of pus ceased and healing took place with unexpected rapidity. Again, in two cases of amputation of the thigh—one (Case 8) for tumor albus in a woman, aged 62 years, the other (Case 9) in a youth, aged 17 years, after a severe compound comminuted fracture of the femur, where abscesses had formed in the stumps during the second week after operation—it was also used with marked advantage. In the former case the suturing broke down rather extensively, partly owing to pus formation and partly owing to sheer deficiency of reparative power. A large granulating surface resulted which was daily syringed with the solution and afterwards dusted with the powder with total inhibition in a few days of all pus formation. The case eventually did well, healing proceeding slowly by granulation. In the other case a small suppurating sinus was closed in a few days by treatment on similar lines.

One of the preliminary experiments suggested the possibility of its being of use for washing out the septic bladder, and accordingly it has been so used in a few cases, with advantage in all and perfect cure in at least one. At the present moment it is being used from time to time in a case which has been demonstrated by the finding of tubercle bacilli in the urine to be one of tuberculous disease of the bladder. The symptoms have certainly improved under its use, but a reasonable doubt may be entertained of its being of any permanent benefit in such cases.[5] The solution has also been used as a vaginal douche and inhibited pus formation in a case of purulent vaginitis of some months' standing. It has also been ordered in chronic urethritis as an injection with satisfactory results. In some cases of eczema, probably those of specific type, it has done well when applied in ointment. In two cases in private practice, however, it proved slightly irritative. These have been the only cases observed in which its use has been in any way disadvantageous. In a large number of cases of injuries of the hands, such as lacerated, incised, or poisoned wounds, in whitlows of all degrees of severity short of actual bone necrosis, and in compound fractures of the phalanges, it has been used with complete success in the dry powder.

Speaking generally, I may say that calcium iodate has been used in almost all cases where iodoform is commonly used. I have not, however, applied it to the cut surfaces of amputation flaps though I have in several cases freely powdered the sutured edges after minor operations for diseased conditions. In all operations where surfaces are left to granulate, such as after curetting, I have used it in powder dusted straight on to the cut surface. In no case when so used has there been the slightest evidence of any irritative or toxic effect. Even children do not complain of any smarting after its use. Adults when questioned reply that it smarts a little after the first one or two applications of it to a raw surface, but after the formation of granulations its application is perfectly painless. Its advantages as compared with iodoform may be summarised as the absence of smell in the substance itself, the checking of fœtor, the prevention of hyper-granulation, and the inhibition of undue formation of pus. Further, it can be used where iodoform is inadmissible—for example, in aqueous solution for such purposes as a gargle or mouth-wash, for washing out the bladder, vagina, or uterus, &c.

Regarding its internal uses I have up to the present had less chance of testing its properties, but personally I can testify to its efficacy in checking fermentative changes in the stomach. I have frequently taken two grains and sometimes repeated the dose a second and even a third time during the same day without inconvenience and always with marked relief of the symptoms. It leaves a slight metallic taste in the mouth after the first few exhibitions, but this is not observed after a time. On the day after a dose of two grains there is a feeling of essential well-being accompanied by increased appetite. For this reason I am inclined to think that apart from its antiseptic action the salt really possesses some tonic properties. Sonstadt, I may say, took as much as 15 grains at one time with only "a slight headache next day, an increased appetite, and generally such effects as might follow an ordinary dose of quinine." He also alleges that he saved himself from an attack of typhoid fever by the timely administration of about a decigramme (one and a half grains) of the salt. This, coming from a layman and nearly 30 years ago, may be taken for what it is worth, but in typhoid fever we have just the conditions under which we might expect its successful use. The fact that the substance liberates chlorine when in contact with hydrochloric acid favours the idea, but I regret that up to the present I have had no opportunity of testing it in this direction, cases of typhoid fever being of notoriously rare occurrence in this neighbourhood.

When ordered for internal administration I should recommend the exhibition of the drug in solution. I have myself experienced—and others have spoken to the same effect—a feeling of heat at the epigastrium after swallowing the dry salt. Sonstadt's maximum dose of 15 grains may be set down as a long way in excess of any possible requirement, and three or four grains may be stated as a fair average dose for an adult.

In conclusion, I may say that during the experimental stage the substance was known by the provisional name of "Calcinol" and that the total supply was prepared by myself or latterly made for me by the local chemists according to the directions already given.

Elgin.

[5] All symptoms have been in abeyance, the urine continuing acid since August 5th, when the bladder was last washed out.

CIRCUMCISION AS A PREVENTIVE OF SYPHILIS AND OTHER DISORDERS.

BY E. HARDING FREELAND, F.R.C.S. ENG.,
SURGEON TO THE ST. GEORGE'S AND ST. JAMES'S DISPENSARY, LONDON.

> "*The prepuce is an appendix to the genital organs the object of which I could never divine; instead of being of use it leads to a great deal of inconvenience, and the Jews have acted kindly in circumcising their children, as it renders them free from one at least of the ills to which flesh is heir.*"—RICORD.[1]

I HAVE no new fact to disclose or theory to propound. The burden of my theme is this: that if it were possible to secure the efficient circumcision of every male in infancy not only would many of the disorders incidental to the genito-urinary organs in childhood, adolescence, and adult life be prevented, but also—a fact of far greater importance—that the incidence of that scourge of humanity, syphilis, which in its ever-varying phases permeates all classes of society at every period of life, would be materially diminished. When, however, one becomes the advocate for the universal practice of an operation which has for its object the wholesale removal of a certain healthy structure as a preventive measure, the results of which, far reaching though they be, can only be looked for in the more or less dim and distant future, one will naturally be expected to adduce good evidence not only that the results justify the operation, but also that the operation is justifiable. In other words, it is necessary to show: (1) that the operation is free from risk; (2) that the deprivation of the structure which it is proposed to remove will not inflict any physical disability on the individual; and (3) that the benefits which are likely to accrue are substantial and commensurate with the sacrifice. The questions which arise out of these propositions I shall endeavour to answer *seriatim*, but as briefly as possible.

1. *Is the operation safe?*—Most of those who are competent to judge, I take it, will agree with the statement that, given a healthy child in the hands of a competent surgeon who adopts every precaution which modern surgery demands, the operation of circumcision is attended with such infinitesimal risk that for all practical purposes it may be considered to be safe.

2. *Does the operation interfere with the physical well-being of the individual?*—From a sanitary point of view it can hardly be gainsaid that the removal of the prepuce is a decided advantage, the permanent exposure of the glans rendering that organ more cleanly and more readily cleansed. But it has been urged as an argument against the universal adoption of circumcision that the removal of the protective covering of the glans tends to dull the sensibility of that exquisitely sensitive structure and thereby diminishes sexual appetite and the pleasurable effects of coitus. Granted that this be true, my answer is that, whatever may have been the case in days gone by, sensuality in our time needs neither whip nor spur, but would be all the better for a little more judicious use of curb and bearing-rein. That circumcision is

[1] Quoted by Watson, Edinburgh Medical Journal, vol. xviii., p. 752.

no bar to procreation is well exemplified by the fact that the Jewish race, who have practised universal circumcision from time immemorial, still survive and show no sign of ceasing to increase and multiply. The Mahomedans,[2] again, among whom the practice is as common as among the Jews, certainly do not seem to suffer from any lack of virility. On general grounds, then, it is safe to conclude that circumcision not only does not interfere with the physical welfare of the individual but that from several points of view it is a positive advantage.

3. *Does the end justify the means?*—It would be sheer waste of time for me to dilate here at any length on the evils which arise from a long, adherent, or constricted prepuce. The effects of these conditions—including as they do dysuria, enuresis, urinary retention, balanitis, constriction of the glans, hernia, rectal prolapse, difficulty in sexual intercourse, aggravation of gonorrhœa, a liability to contract evil habits, together with a whole host of nervous symptoms, more or less severe, which follow in their train—are, or should be, well recognised. Every surgeon knows how readily these conditions can be relieved—and if relieved then prevented—by circumcision.

But if these were the only troubles which it was sought to obviate by the practice which I am advocating, I fear that it would find but few adherents, as, no doubt, these ailments can be effectually dealt with as they arise. Unfortunately, however, the matter does not end here, and the prevention of these ailments, although a matter of no small importance, sinks into insignificance in comparison with the great result which it is sought to attain—namely, the prevention of syphilis This is the point to which I wish to direct special attention, and the remainder of this paper will be devoted to adducing what evidence I can to prove that the universal practice of circumcision would have the effect of reducing the case-incidence of syphilis in a substantial degree.

Before going into details I should like to refer very briefly to the general effects produced by the changed anatomical relations of the parts which exist after circumcision. Under normal conditions the prepuce covers the glans like a hood and consists essentially of a reduplicated fold of skin, the outer surface of which is continuous with the general tegumentary covering of the penis, while the inner or inverted surface is continuous with the skin covering the glans, forming the retro-preputial fold behind and the frænum below. After circumcision the glans is exposed, the retro-preputial fold is everted and obliterated, and the frænum, if the operation is efficiently performed, ceases to exist. Thus the various pocket-like folds which formerly existed around the glans and favoured the retention of secretion are smoothed out, and thereby the risks of irritation and excoriation, as well as the implantation of disease germs, are reduced to a minimum. Again, the dry, somewhat thickened, condition of the epithelium of the glans which is observed after circumcision, due no doubt to the combined effects of exposure to the air and slight friction of the clothes, offers an additional barrier to any local infection. Indeed, anyone who has taken the trouble to compare the dry, pink-parchment-like, cleanly appearance of the glans of the circumcised with the sodden, swollen, uncleanly structure which is frequently presented to view when the prepuce of the uncircumcised is retracted cannot fail to have been struck by the contrast. In the latter case the space between the prepuce and the glans forms the very *beau ideal* of a place for the implantation and multiplication of bacteria of all kinds, the pent-up secretions furnishing them with an efficient nutrient medium in which to grow, the heat and moisture favouring their development, and the excoriations which are so liable to exist forming a ready means whereby their products may gain access to the general circulation. But my readers will expect me to bring forward more tangible proofs than vague general inferences.

Although it seems to be the prevalent opinion that syphilis is less common among the Jews actual statistics are few. Jonathan Hutchinson,[3] however, gives the following analysis of 330 cases of venereal disease among hospital patients, about one-third of whom were Jews.

—	Total venereal cases.	Gonorrhœa	Syphilis.
Not Jews	272	107	165
Jews	68	47	11

This table serves to show not only that the incidence of syphilis is far less frequent among the Jews but that the incidence of gonorrhœa is far more frequent, thus clearly proving that their comparative immunity from syphilis is not due to their excessive morality, but rather, in the absence of any other reason, to circumcision.

My own experience completely bears out the idea that syphilis is less prevalent among the circumcised, although unfortunately I have no figures to adduce. During the three years in which I served as surgeon to the Peninsular and Oriental Steam Navigation Company I never remember to have seen a primary syphilitic chancre among the Lascar crew, who being Mahomedans are circumcised to a man, while among the Sedi boys, who for the most part grow long foreskins, primary sores were not uncommon, nor were the European crew exempt. Other venereal diseases were prevalent among the Lascars, so that their immunity could not be ascribed to any greater morality on their part. I was much struck at the time by the apparent immunity of the Lascar to syphilis, and could only ascribe it to his having the good sense to follow the example of the Prophet and be circumcised.

Granted for a moment that universal circumcision is likely to cause a reduction in the case-incidence of syphilis, the next question to be considered is what amount of reduction is likely. For obvious reasons the vast majority of primary syphilitic lesions (according to Julien[4] about 94 per cent.) occur on the genitals, and all observers from the time of John Hunter[5] onwards are agreed that in the male the seat of election for the primary sore is the prepuce. As to the part of the prepuce which is most commonly affected there seems to be some divergence of opinion, some giving the inner surface of the prepuce and others the retro-preputial fold the precedence. According to Jonathan Hutchinson[6] "the most frequent position for chancres is the prepuce (reverted) just behind the corona ('the furrow')."

To show the relative frequency with which the primary lesion occurs on the prepuce, as compared with primary genital lesions in the male occurring elsewhere, I append the subjoined table which I have compiled from the statistics of three well-known observers.

Observer.	Number of initial lesions.	Number on the prepuce and furrow.	Percentage on the prepuce and furrow.
Fournier[7] ...	423	314	74·2
Clerc[8]	325	234	71·6
Berkeley Hill[9]	150	111	74·0
Total	898	659	73·3

Probably the veriest enthusiast would hardly claim that the whole of this 73·3 per cent. of genital chancres in men could be prevented by circumcision, however skilfully performed or however universal. Most, however, would be inclined to admit that it would be possible to prevent practically all chancres occurring on the prepuce proper and a variable number of those at the retro-preputial fold (furrow). Unfortunately, in the statistics of Fournier and Clerc quoted above these two classes are massed together and no conclusion can be drawn as to their relative frequency. Of Berkeley Hill's[10] 150 cases, 70, or 46·6 per cent, occurred on the prepuce proper, and Jonathan Hutchinson, jun.,[11] out of a series of 125 genital chancres found that 25 per cent. occurred on the prepuce. While the former estimate is probably considerably above the average the latter is possibly somewhat below. Taking, however, the lower percentage as correct, one may conclude, according to the above statistics, that the universal practice of circumcision should reduce the case-incidence of genital syphilis in the male by something between 25 per cent. and 73 per cent, or, taking a mean of these, by 49 per cent. But, striking as these figures undoubtedly are, they by no means represent the whole result.

Everyone who suffers from syphilis in its infectious stages becomes a potential focus of infection and a source of danger to others. Conversely, every case of syphilis prevented becomes a potential source of prevention and a safeguard to others. Thus circumcision may not only confer a benefit upon the circumcised but also on others with whom he may come in contact. Unfortunately, it is quite impossible to bring any direct numerical evidence to bear upon this point, but a hypothetical case, based on a very moderate computation, will serve to show how in a very short space of time one focus of infection may grow into several hundred. Take, for example, a man with a syphilitic chancre on the prepuce; in all probability he will sooner or later infect some woman, who, if he be single, is likely to be of the prostitute class Supposing this to occur, the woman, in all human probability, will in due course infect several other men, who, in their turn, will infect as many women, each of whom again is likely to infect several more men, and so on, the disease being spread and the numbers increasing with alarming rapidity. When one considers that the primary source of infection might have been prevented by circumcision, and that the whole series of cases which have been assumed to follow in its wake each in their turn become fresh sources of infection, capable under favourable circumstances of producing like results, it becomes impossible to estimate the number of cases which might be prevented by circumcision, if universally practised. All that can be said is that if the immediate effects are great the remote effects must be far greater

But, again, the matter does not end here. In syphilis it is not only the guilty who suffer, but the innocent suffer with the guilty and the sins of the fathers are in very truth visited upon the children. Deplorable as such a state of affairs may be, it is nevertheless far from uncommon for a married man to infect his innocent wife, and through her his offspring which is yet unborn. Is there any direct evidence to show that the practice which I am advocating will materially diminish this massacre of the innocents? Fortunately there is. Jonathan Hutchinson[12] found that out of 97 female hospital patients who came under his observation in one year for venereal disease 92 were Christians and five were Jews. Of the former 61 were married, and at least two-thirds of these had apparently contracted syphilis from their husbands. Again, the same observer[13] found, out of 252 children under five years of age who came under his care in the course of a year, 179 Christians, giving 27 cases of congenital syphilis, and 73 Jews, giving only three cases of congenital syphilis. These statistics clearly show an enormous reduction in the case-incidence of syphilis among the women and children of the circumcised Jews, and in view of what has already been said the only deduction which can reasonably be drawn from their study is that if the practice of circumcision were to become as general among Christians as it is among their Jewish brethren a proportionately great reduction of the case-incidence of syphilis would take place among their women and children In other words, a not inconsiderable number of innocent women and children would be spared the indignity of being doomed to suffer, through no fault of their own, from a loathsome and lifelong disease—a no mean result, whether considered from a sentimental or practical point of view, and one which, in the absence of any other reason, should amply prove that "the end justifies the means"

Before concluding, however, I should like to say a few words about the operation itself. Simple as the operation is, certain details must be observed in its performance if the result is to be successful for the special purpose which one has in view. It must ever be borne in mind that the special object to be attained by circumcision as a preventive of syphilis is not only the removal of the prepuce, but, as far as possible, the obliteration of all folds about the glans. The advice usually given to the novice is to be careful not to remove too much skin. Consequently too little, rather than too much, is often removed. The result is that the retro-preputial fold still persists, a matter of some moment from the present point of view. The incision should be made in such a way as to be oblique from above downwards and forwards, and slightly concave forwards so that when the skin retracts it may sit snugly behind the corona. In other words, the plane of the incision should be as nearly as possible parallel to the plane of the corona. The reflected layer of the prepuce—the so-called mucous layer—which has been left untouched by the first incision, should, after being slit up and reverted, be carefully trimmed around the corona glandis in such a way as to allow the cut edge to come neatly into contact with the cut edge of the part first removed. A wedge-shaped piece of the frænum should always be removed. By so doing the folds which exist on either side are obliterated and the œdematous nodule which is liable to form at this point is prevented All rough and unnecessary manipulation is to be avoided, as, the cellular tissue being very loose, œdema is easily produced, which not only retards healing but becomes a source of anxiety to the child's friends. Whether my premisses are correct and my deductions sound I must leave others to judge. If they be so, then it becomes the imperative duty of everyone who is cognisant of the facts to exert his influence for the benefit of humanity at large by securing, as far as possible, the efficient circumcision of every male child who comes under his notice. For my own part I am convinced that any community among which syphilis is rife and which imposes upon itself the obligation to circumcise every male child who appears in its midst will confer a great and lasting benefit upon its members, both present and yet to be, at an infinitesimal outlay

Beaumont-street, W.

ON A NEW METHOD IN THE DISCISSION OF SOFT CATARACTS.

BY PERCY DUNN, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL.

THE present-day method of treating soft cataracts by discission is to use a very fine cataract needle, to make a small incision in the capsule of the lens, to employ care not to break up the lens substance too freely, particularly to avoid allowing any of the aqueous to escape during the procedure, and, in short, to aim at securing a gradual absorption of the soft lens matter from the anterior chamber. The effect of this gradual absorption is that some months generally have to elapse before the process is completed. Occasionally, moreover, it happens that the operation has to be repeated owing to the process of absorption having been arrested by the cicatrisation of the capsular wound. Thus further time is lost before the whole lens matter is absorbed and the object of the operation is attained. The disadvantage of this loss of time is obvious, but the procedure has another drawback. There is the possible risk of the swelling of the lens, caused by the imbibition of the aqueous, giving rise to increased intra-ocular tension, necessitating further and immediate interference.

Reflecting, therefore, as I have done for some time, upon these facts, it seemed to me that the operation of discission as practised in the present day by no means fulfilled the requirements of the surgeon and that it was capable of improvement. As a matter of fact, the point upon which the present method of discission wholly hinges is that of the fear of causing glaucomatous symptoms by a too free disturbance of the lens substance It is clearly for this reason that only a limited incision is made in the capsule and care is exercised to secure that only a small quantity of soft lens matter shall escape into the anterior chamber at a time.

The first consideration, then, which seemed to demand attention was how to deal with this risk of the occurrence of increased tension The solution of the problem quickly presented itself. All that was necessary in order to meet the difficulty appeared to be to allow the aqueous to drain away from the anterior chamber before withdrawing the needle. The conclusion is plain that with the aqueous removed any further rapid swelling of the lens would be impossible, and with the globe in a condition of minus tension owing to the loss of the aqueous the subsequent restoration of the anterior chamber would necessarily depend upon the degree of swelling of the lens which was present and upon the amount of soft lens matter which was free and ready for absorption. To put the same matter differently, it is reasonable to conclude that the condition of the lens after the needling would determine the degree of the restored tension.

---

[12] Medical Times and Gazette, Dec. 1st, 1855.

[13] Ibid.

With a swollen lens the aqueous would probably only be re-secreted to the amount which was needful to restore the tension to the normal, and thus it might come to pass that part of the latter might be due to the swollen condition of the lens and the presence in the eye of broken-down soft lens matter, and part to re-secreted aqueous. For this reason, therefore, it is not possible to conceive that glaucomatous symptoms could arise under these circumstances—that is to say, after the aqueous had been allowed to escape at the time of the operation. This assumption is based upon the fact that the intra-ocular tension of a healthy eye is regulated by its requirements; in other words, the lower the tension the greater is the secretion of aqueous, the higher the tension the less the secretion. Thus, assuming these premisses to be correct, three advantages could be claimed for this new method of procedure: (1) the avoidance of the risk of causing increased tension; (2) the possibility of freely breaking up the lens; and (3) the rapid absorption of the soft lens matter.

But, again, a lowered tension must imply a more rapid circulation of fluid through the eye, and it is precisely that condition of affairs which is most to be desired in cases of discission, for the more rapid the circulation of the intra-ocular fluid the more rapid must be the absorption of the soft lens matter. Quite possibly the slowness of the absorption following the present-day method of discission is partly, if not greatly, due to the persistence of a slightly raised tension which causes the circulation of the intra-ocular fluid to be a leisurely process.

It was not long before the opportunity occurred to me of putting these conclusions to the test. The case was that of a child whose right lens I had needled some months previously for congenital cataract. Only one needling was necessary, but at least three months elapsed before the pupil was black. The operation upon the left lens was considerably delayed owing to the supervention of an attack of scarlet fever. When, however, the child had made a good recovery from this, I proceeded to operate upon the second eye as follows:—

Chloroform having been administered I took a broad, instead of a fine, cataract needle, and the pupil being well under atropine, I passed the former into the anterior chamber and the lens, making a vertical and horizontal incision in the capsule. I then freely broke up the lens and afterwards withdrew the needle until the point only remained in the anterior chamber. Next, I partly turned the needle *on its axis, by which I allowed all the aqueous to escape* slowly from the eye. The globe and conjunctival sac were thoroughly douched with chinosol (1 in 4000); some drops of atropine of the strength of two grains to the ounce of water were instilled, and a pad of chinosol gauze and a bandage were applied. The result of the operation was as follows. There was no reaction; in four days' time the pupil was quite black, and all that was left of the lens was a small quantity of soft lens matter lying at the bottom of the anterior chamber. After the lapse of 14 days there was merely a trace of this lental remnant to be seen.

The above facts speak for themselves. They show, I think, that the rapid absorption of soft lens matter from the anterior chamber is only possible when the intra-ocular tension has been reduced by the removal of the aqueous.

A word may now be said regarding the possibility of any untoward effects following the evacuation of the aqueous under these circumstances. The first and only complication which suggests itself is that of iritis, and it might be supposed that in the event of its supervention its origin would be due to mechanical irritation caused by the presence of the broken-up lens matter. But the doctrine that mechanical irritation *per se* can excite inflammation anywhere in the tissues is not one which, in the present day, receives support from scientific testimony. I cannot, therefore, conceive how iritis could occur in these cases unless there was a failure to secure strict antisepticism at the time of the operation.

Some confirmation of the expediency of allowing the aqueous to escape in the discission of soft cataracts occurs in many cases of extraction operations for senile cataract. In these cases no difficulty is experienced in obtaining the fairly rapid absorption of the lental débris which it has been found impossible to remove after the extraction of the lens—a result which, I believe, must be chiefly due to the lowered tension in the eye caused by the necessary steps of the operation.

Wimpole street, W.

A CASE OF HYDATIDS PRIMARILY AFFECTING THE LUNG.

By JULIUS CÆSAR, F.R.C.S. IREL., L.R.C.P., L.R.C.S. EDIN.

THAT hydatids primarily affecting the lung are exceedingly rare is evidenced by the very brief reference made to them in those works which discuss the matter, some writers stating that they are hardly ever met with and others ignoring the subject altogether. Mr. Norman Porritt in his work on "Intra-Thoracic Effusion" gives but one case.

That the following case was one of hydatids originating in the lung will, I think, be beyond dispute after a consideration of the following facts. 1. The liver was of normal size. 2. The hydatids could not have originated in the pleura, as had they done so, according to Dr. Clifford Allbutt, the costal and pulmonary pleuræ would have become fused, but I was able to sweep my hand round the inter-pleural space. 3. There was no discoverable communication between the abdominal and pleural cavities. 4. I found the growth springing from, or attached to, the base of the lung. There was nothing in the history of the patient to suggest the source of the infection beyond the fact that some six years ago she was laid up for about nine months with what her medical attendant stated to be blood-poisoning from drinking foul water. She never lived where dogs were kept (i.e., kennels) or out of England. She was said to have complained for some years of a pain in her right side, but this was not severe enough to induce her to seek advice for it.

The patient first came under my care in July, 1900, complaining of vomiting, diarrhœa, and severe pains shooting across her abdomen. By the end of a week these had completely subsided and she resumed her domestic duties and continued to perform them up to August 10th, when she was suddenly seized with a recurrence of these symptoms and in addition she complained of shortness of breath and of expectoration of a clear viscid fluid. Her respirations were 36, her pulse was 94, and her temperature was 98° F. Auscultation revealed nothing to account for the dyspnœa and percussion only doubtful dulness at the base of the right lung. Vocal fremitus and vocal resonance were normal. On the 11th the patient was in much the same *state except that the bowels were more relaxed; the expectoration* was, if anything, more viscid and was accompanied on two occasions by a distinct streak of blood which showed no inclination to spread. On the 12th she had a very bad attack of dyspnœa which lasted for a few hours and then subsided. The pain was decidedly more localised to the right side. The vomiting had ceased and the bowels were less relaxed. On the 13th her breathing was much easier but the expectoration continued and looked like the partially coagulated white of an egg. The dulness was more definable. The respirations were 30, the pulse was 80, and the temperature was 98°. On the 14th she was much the same; the bowels acted normally. For the next three days her state did not materially change except that she had to be propped up in bed to assist her breathing and the dulness had become more marked and the dyspnœa more frequent. She had no bad attack of dyspnœa on the 18th, but she could not lie down because of the cough and the expectoration. The latter had become very viscid and was always accompanied by the streak of blood. The dulness reached to within two fingers' breadth of the inferior angle of the scapula, below which point vocal fremitus and vocal resonance were abolished. The respirations were 40, the pulse was 86, and the temperature was 98°. She had a very bad day and night on the 19th, the dyspnœa, cough, and expectoration being incessant and quite prostrating her after each attack. The temperature rose to 99°, which was the highest point it had as yet attained. The symptoms having undergone no improvement since the 19th, on the 20th I tapped the thorax at the ninth interspace a little behind the axillary line, and withdrew about two and a half ounces of pale sherry-coloured gelatinous substance which the microscope showed to be broken-down hydatid cysts without hooklets. During the operation the patient's breathing became much embarrassed and she nearly fainted. On the 21st the tapping did not appear to have afforded her relief. Her temperature rose to 100° and fine râles were heard in front just below the right nipple.

As the surroundings of the patient were not conducive to her comfort or the success of an operation I advised her to go into the union infirmary, but she put it off from day to day until Sept 6th when she was admitted. In the meantime her condition had gone from bad to worse; her strength began to fail, the râles in her lung to get louder and coarser, and she expectorated yellow phlegm. The temperature was 100°, the respirations were 40, and the pulse was 90. On the 9th I was about to make an incision in her side in hopes of giving her at least temporary relief, but her breathing became so embarrassed that I was obliged to desist. Her temperature on this day reached its highest point (101°) and remained at that point until her death on the 11th.

Twenty-four hours after the patient's death I made a restricted post-mortem examination, as I could not get permission to do more. I opened the chest through an incision along the ribs and through the attached diaphragm I examined the seat of entrance of the trocar and found no trace of it on the inside; but about a pint and a half of a yellow gelatinous fluid, consisting partly of cysts varying in size from a threepenny piece to that of a five-shilling piece and looking like nothing so much as slightly yellow-tinged jellyfish, with a little pus towards the end, flowed out.

I think there are several points of interest in this case, apart from its rarity, as regards diagnosis: 1. The very low temperature, which was never above 100°, up to within a couple of days before death. 2. The character of the expectoration with the well-defined streak of blood. 3. The intermittent and severe dyspnœa. 4. The diarrhœa. 5. The fact of the patient having years before suffered from drinking foul water. Dr. Clifford Allbutt in his "System of Medicine" refers to all these points as being characteristic, and I think they go a very long way towards differentiating it from pleurisy with effusion or empyema, and its being confined to one side would, I think, be sufficient to exclude hydrothorax.

Minster, Sheerness.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PUERPERAL FEVER SUCCESSFULLY TREATED WITH ANTISTREPTOCOCCIC SERUM.

By HERBERT E. WALLER, M.R.C.S. ENG., L.R.C.P LOND.,

AND

FRANCIS R. GIBBS, M.R.C.S. ENG., L R C.P. LOND.

THE patient, who was a primipara, 23 years of age, was confined on Nov. 25th, at 9 P.M. It was a difficult high forceps case, the presentation being occipito-posterior and the head not well flexed. The cervix uteri was torn in two places, but not to any considerable extent, and the perineum was ruptured. Two stitches were inserted and full antiseptic precautions were observed throughout. The patient suffered a good deal from shock, having been in labour fully 36 hours. A vaginal douche of solution of corrosive sublimate (1 in 2000) was given next morning. On the morning of Nov. 28th (the third day after delivery) the patient had a pulse of 120 per minute and a temperature of 102·8° F. She had had several rigors during the previous night; the uterus was tender, and the tongue was tremulous. An enema was given and was followed by a good action of the bowels. By night the temperature rose to 104° and the pulse was 180 and irregular, sometimes beating at the rate of 200 and only to be counted with certainty by using a stethoscope. The uterus was accordingly well irrigated with the same solution as before by means of a long channelled glass tube. The lochia were scanty and offensive. Tincture of digitalis in doses of five minims every four hours and brandy at the rate of six ounces in 24 hours were given. On the 29th the temperature was still 103·6° and the pulse was 150. She was taking her food well and appeared remarkably well throughout, a feature in itself by no means cheering. Another intra-uterine douche was given and the serum treatment was commenced, six or seven cubic centimetres of antistreptococcic serum being given in the morning as a first dose. 20 grains of sulphate of quinine were given in two doses during the day, some dizziness and slight deafness resulting. The bowels were loose during the day, being opened four times. In the evening the temperature was 103° and the pulse was 159. The skin was cool and moist. The uterus was again washed out and the perineal wound, which was sloughy, was painted with silver nitrate solution; 10 cubic centimetres of serum were injected and 15 minims of tincture of digitalis were given every four hours together with chalk mixture for the diarrhœa. Brandy was continued at the same rate as before. On the 30th the temperature was normal, but the pulse was still 120. 10 cubic centimetres of serum were injected, the uterus was washed out morning and evening, and the other treatment was continued as before, but with the omission of the quinine. In the evening the temperature was 99·4° and the pulse was 116. On Dec. 1st the morning temperature was normal and the pulse was 104, the evening temperature being 99·8° and the pulse 120. 10 cubic centimetres of serum were injected in the morning and a uterine douche was given morning and evening. The patient was drowsy throughout the day and it was decided to wait a day before giving a further injection of serum. There was no subsequent rise of temperature and recovery was uninterrupted. The injection of the antistreptococcic serum produced no local symptoms other than a slightly raised irritating erythema which occurred a few days afterwards and lasted only a few hours.

Previously we had tried the antistreptococcic serum on only two cases, both of which terminated fatally. One of these patients was a young woman suffering from puerperal fever who came under our care several days after delivery. She had been having uterine douches twice daily, but the antistreptococcic serum was not used till the third or fourth day after delivery, and did not seem to exert any influence. The patient preserved that characteristic absence of subjective symptoms which has been marked in every case that has come under our notice. A few days before her death, when her temperature was 106° F., she sat up in bed playing with the baby and professed herself "All right to-day, thank you" The other case was that of a man, aged 81 years, who had his superior maxilla, including the contents of the orbit, removed for sarcoma of the antrum. Hæmorrhage was very free and the actual cautery had to be used. The patient was a very hearty old man and stood the operation well, but, unfortunately, erysipelas set in in a few days afterwards. We tried the serum on the next day, injecting 20 cubic centimetres at first and 10 cubic centimetres daily afterwards, but no good seemed to result, and the injections gave rise to considerable pain locally, so the treatment was abandoned. The old man only survived a few days more.

The success in the treatment of the third patient (the case described above) was due, we believe, to the early injection of the serum, which was ordered by telegram from, and sent immediately by, Messrs. Burroughs and Wellcome. It will be observed that the first douche produced probably no effect, as the fall in temperature from 104° on the evening of Nov. 28th to 103·6° on the morning of the 29th was, perhaps, only natural. The first dose of serum, accompanied by a douche, produced a slight effect—namely, a fall in temperature from 103·6° in the morning to 103° at night. The second dose (and douche) produced a fall in temperature from 103° at night to normal in the morning, and under continuance of the treatment the temperature did not again reach 100°. No bacteriological examination of the blood was made, but the symptoms of the onset of the malady were as well marked as in any case which we have been unfortunate enough to witness.

Bourne End, Bucks.

INFECTIVE PAROTITIS AFTER ABDOMINAL SECTION AFFECTING TWO OTHER MEMBERS OF A FAMILY.

By BERTRAM ADDENBROOKE, M.D. DURH., M.R.C.S. ENG.

THE history of the following cases is, I venture to think, of the greatest interest.

On Nov. 5th, 1900, I performed the operation of abdominal section on a boy, aged 13 years, who suffered from suppurative peritonitis (non-tuberculous). Three days after the operation he complained of pain and stiffness in the region of the left parotid gland. This soon spread to the right side, and within 24 hours he was suffering from a severe attack of double parotitis, a somewhat rare though recognised complication after abdominal section; the parotitis gradually resolved and no outward traces of the attack remained after Nov. 13th. On Nov. 21st an aunt of the patient visited him and stayed with him for about an hour and a half, kissing him both on entering and leaving the room; she had walked about seven miles to see the boy and she walked the same distance home again. On reaching home she complained of feeling very tired. Previously to this visit she had not seen the boy since an hour before the operation. *On Nov. 24th* (three days after her visit) she complained of stiffness in the region of the parotid glands and developed double parotitis, which gradually resolved. On Nov. 27th the sister of the last patient, with whom she was living, also complained of stiffness in the region of the parotid gland and she developed likewise, in a few hours, a mild attack of parotitis which also in a few days subsided; this third patient had never been in contact with the original patient at any period of his illness. I inquired most carefully for any cases of parotitis epidemica (mumps) in the neighbourhood where these patients lived, but failed to elicit any history of such. I would suggest that the two attacks of parotitis, in the aunt and her sister respectively, were due to direct infection, and hence the rapidity of the onset of illness after being inoculated, the infection travelling down Stenson's duct to the mouth of the boy, thence to the aunt, and then by the same route *from the aunt to her sister.*

Metastasis is, I venture to think, not a very satisfactory explanation either of the parotitis that occurs after abdominal section or of the well-known orchitis that follows after mumps, although it is the best one we have. If, however, the operation was, by metastasis, the determining cause of the parotitis in the boy, there was a very striking point in connexion with these cases—namely, (1) three days after the operation (the determining cause) the boy developed parotitis; (2) three days after visiting the boy the aunt developed parotitis (having rendered herself by over-exertion and fatigue less resistant to infection); and (3) three days later the sister developed the same affection, evidently having caught it from the previous patient (the boy's aunt). In all of these there is the definite incubation period of three days. Had these cases of parotitis suppurated, cultures might have been made and some evidence as to the connecting links between the cases obtained, but fortunately for the patients themselves, suppuration did not occur. I have been unable to find any record of similar cases, and I hope that some of your readers may be able to throw some light on an interesting pathological condition.

Kidderminster.

MEASLES AT SWANSEA.—At the meeting of the Swansea Sanitary Committee held on Dec. 17th the medical officer of health, Mr. E. Davies, reported that 29 deaths from measles had occurred during the past nine weeks and that five of the elementary schools in the town had been closed owing to the epidemic. Mr. J. A. Rawlings remarked that measles ought to be included in the list of notifiable diseases, and it was eventually decided that notice to that effect should be given.

BRISTOL MEDICAL MISSION.—At the meeting of the Bristol Medical Missionary Society held on Dec. 18th it was stated that during the past 12 months 8310 patients had been treated against 7535 in 1899, and that of this number more than 2000 had been attended at their own homes. The expenditure for the year amounted to £726 and the income to £643. The adverse balance of the mission now amounts to about £300 and a special effort is to be made to raise that amount.

INFANTILE MORTALITY AND HEREDITARY SYPHILIS.—At the meeting of the Stonehouse (Plymouth) District Council held on Dec. 11th the medical officer of health (Mr. T. Leah) reported upon the infantile mortality, which is higher than the average throughout the county of Devon. Stonehouse is the most densely populated town in the area of the Devon County Council and Mr. Leah stated that the density of the population was one of the causes of this mortality, while he added that hereditary syphilis was decidedly on the increase since the Contagious Diseases Act was repealed.

ANCOATS HOSPITAL, MANCHESTER.

A CASE OF MELANOTIC SARCOMA OF THE LIVER; WITH REMARKS ON THE DIAGNOSIS OF MELANOTIC TUMOURS OF THE INTERNAL ORGANS.

(Under the care of Dr. R. T. WILLIAMSON.)

MELANOTIC sarcoma of the liver is nearly always secondary, though some very definite cases have been recorded in which it appeared to be primary.[1] The association of the affection of the liver with the same form of growth in the eye is frequent and only a short time intervenes between the primary eye affection and the appearance of the disease in the liver, as in the case recorded below, but in one case the interval between the removal of the eye and death from the growth in the liver was 10 years.[2] As in Dr. Williamson's case, it is not rare for secondary sarcomatous growths of the liver to give rise to a uniform enlargement in which no individual tumour masses can be felt.

A girl, aged 16 years, was admitted into the Ancoats Hospital on Sept. 13th, 1900, on account of enlargement of the abdomen. Three months before admission her sight had commenced to fail in the right eye and in a short time vision was lost in this eye. The eye was removed, on account of intra-ocular tumour, by Mr. E. Roberts, surgeon to the Manchester Royal Eye Hospital, five weeks before the patient's admission to the Ancoats Hospital. Four weeks after the operation she first noticed the swelling of the abdomen.

On admission the patient was fairly well nourished. There was no jaundice and no pigment spots or tumours were present in the skin. The temperature was normal. There was no œdema of the legs. Nothing abnormal could be detected in the heart and lungs. The liver was very much enlarged; its upper limit reached as high as the fourth rib; its lower edge extended down to the iliac crest on the right side and could be felt below the umbilicus in the middle line. The lower edge of the liver was sharp and even. The surface of the liver was quite smooth and firm. The hepatic enlargement was uniform. There was no hepatic pain or tenderness, and there was no ascites. The spleen was not enlarged. The patient vomited occasionally and suffered from diarrhœa. There was no hæmatemesis.

The urine was slightly darker than normal urine when freshly passed, but it had only a slight brownish tinge. When allowed to stand exposed to the air for several days, however, it became black in colour, but when kept in a corked bottle it had not changed its colour at the end of seven weeks. The specific gravity was 1015 and the reaction was acid; albumin and sugar were absent. The addition of nitric acid to the urine produced a deep black coloration with a slight brownish tinge. A solution of perchloride of iron produced a deep black coloration. Sulphuric acid and bichromate of potash also produced a deep black coloration. These are the reactions for melanin. There was no reaction of the urine for blood pigment with tincture of guaiacum and ozonic ether and no hæmin crystals could be obtained. A deep Prussian blue coloration was obtained on the addition of nitro-prusside of sodium, liquor potassæ, and acetic acid.

During the four weeks that the patient was in hospital she gradually lost flesh. At times she suffered from severe pain in the abdomen *chiefly in the region of the epigastrium.* At other times the pain was absent and on these occasions, even at the end of the illness, the liver was painless on palpation. Towards the end of the patient's illness the feet were slightly œdematous, but there was never any ascites. There was no jaundice until the last day of life when the conjunctivæ presented a slight yellow tinge. Death occurred on Oct. 15th.

---

[1] Delepine: THE LANCET, Jan. 24th, 1891, p 196.
[2] Loc. cit.

Necropsy.—At the post-mortem examination none of the organs presented any pathological changes of importance except the liver. The liver was greatly enlarged, extending down to the iliac anterior superior spine. The enlargement was uniform; the lower margin was sharp and the surface was smooth. The weight was 13¼ pounds. On section the whole organ was infiltrated with tumour growths. In most parts the liver substance was studded with small, roundish patches of tumour growth varying from one eighth of an inch to half an inch in diameter; in some parts the liver substance was infiltrated with extensive, deep, black patches of tumour growth. At many points close to the pigmented patches and nodules were other nodules of tumour growth of a bright, white colour. The kidneys were normal with the exception of one small melanotic nodule of the size of a pea The spleen was not enlarged. The stomach and intestines were compressed greatly by the enlarged liver but otherwise appeared to be normal. The thoracic organs presented no changes of importance. The blood, both during life and post mortem, gave no reaction for melanin with nitric acid or perchloride of iron. Microscopically sections of the liver at the parts infiltrated with tumour growth presented the appearance of a melanotic sarcoma, composed chiefly of pigmented spindle cells. The white nodules of tumour-growth presented the appearance of a non pigmented spindled-celled sarcoma.

Remarks by Dr. WILLIAMSON.—The clinical diagnosis of melanotic sarcoma of the liver was practically certain, being based on the history of removal of one eye for tumour growth, the enlarged liver, and the presence of melanogen in the urine which gave the black coloration with nitric acid and perchloride of iron. In the *Medical Chronicle*, October, 1899, I recorded a similar case of melanotic sarcoma of the liver secondary to a primary growth in the eye, and also a case of multiple melanotic tumours of the brain secondary to a pigmented tumour of the skin: both of these cases were under the care of Dr. Graham Steell at the Manchester Royal Infirmary, where I had the opportunity of observing them when medical registrar.

With reference to the clinical diagnosis of melanotic tumours of the internal organs, it is interesting to note that they are usually secondary to primary disease of the eye or skin. Hence superficial inspection of the patient often furnishes the most important indication in diagnosis. The absence of one eye and the history of its removal for tumour, or the presence of a pigmented scar in the skin, and the history of the removal of a dark-coloured tumour of the skin often indicate the correct diagnosis. The presence of small pigmented patches or small pigmented tumours in the skin is another point of diagnostic value. These patches or small tumours are deep-black or bluish-black in colour. They were absent in the case recorded above, but were present in the two other cases which I published 12 months ago. The liver, when affected by secondary melanotic tumour, is often very greatly enlarged, especially when the primary growth is in the eye. In the case just recorded the liver weighed 13¼ lb.; in the other case previously published it weighed 16¼ lb. Ascites was absent in both of the cases I have seen. In one of the cases jaundice was entirely absent; in the other it was absent until the last day of life, when there was a slight yellow tinge of the conjunctivæ. In both cases pain was absent for a long period at first

In two of the three cases which I have examined the urine contained melanogen and gave the reactions for melanin—a deep black-brown coloration with nitric acid and a deep black coloration with perchloride of iron. With respect to the diagnostic value of melanuria, it may be here mentioned that the same marked reactions are said to be obtained occasionally, but very rarely, in the urine in wasting diseases, when no melanotic sarcoma is present. But since nitric acid is used so frequently in urine testing the occurrence of such a marked black-brown reaction must be extremely rare, or it would have been recorded more frequently. The blue reaction with nitro-prusside of sodium, liquor potassæ, and acetic acid is not due to melanin but to some other substance.

When the reactions for melanin are obtained in the urine with perchloride of iron and with nitric acid there is always a strong probability that melanotic tumours are present in the internal organs. This probability is increased and the diagnosis is almost certain if there is in addition (1) great enlargement of the liver, (2) if small pigmented patches or tumours are present in the skin, or (3) if there is a history of the removal of one eye for intra-ocular tumour, or of the removal of a pigmented tumour of the skin When the urine does not give the reactions for melanin the diagnosis of melanotic tumours is still indicated if, along with symptoms of tumour growths in the internal organs, there are scattered small black patches or nodules in the skin (as was the case in the melanotic tumour of the brain already referred to).

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Dec. 7th at the West London Hospital, Dr. F. SCHACHT, the President, being in the chair.

The minutes of the last meeting were read and confirmed and several new members were elected.

The PRESIDENT said it was his sad duty to allude to the death of one of the society's vice-presidents, Dr. Symons Eccles. He had held every office in the society and the members were well aware of the energy and enthusiasm which he put into the work of the society and he was sure that they would all feel his loss. He, together with the two secretaries and the treasurer and editor of the journal, had attended Dr. Eccles's funeral as representatives, and he proposed that the meeting should pass the following motion:—

> That this meeting desires to record the loss sustained in the death of Dr. Symons Eccles, one of its vice-presidents, and wishes to convey to Mrs. Eccles its sincere sympathy.

This was carried in silence.

Dr. LEONARD DOBSON then showed a case of Raynaud's Disease. The patient was a man, aged 45 years; he had always been healthy until he had an attack of influenza seven years ago. He shortly afterwards lost all his money and lived a life of great anxiety and privation. He first noticed that his hands became cold and the fingers suppurated. The disease rapidly became worse and now the hands were always cold, were bluish in colour, and the finger-tips were ulcerated in the winter. The disease was symmetrical and the thumbs were not affected. One ear was becoming affected, but the feet were not attacked. The hands were worse after exposure to cold or after a meal; they then became first white and afterwards purplish black. The urine was normal; the discs were normal; there was no specific history. He was at present being treated with galvanism and strychnia and was improving.—Dr. DOBSON, in reply to questions from Dr. SEYMOUR TAYLOR and others, said that his patient had not suffered from oxaluria or hæmoglobinuria. He had not yet tried liquor trinitri as the patient was satisfied with his present treatment.

Dr. TAYLOR showed a case of Transposition of all the Viscera in a male. He thought that the cause of this was very obscure, but gave as a theory that the man was possibly a twin, the other twin being possibly a blighted ovum, and that if the twins were of the same sex that there might have been a longitudinal segmentation of the cells of the embryo.—Dr. ROSS SINCLAIR also showed a girl who was the subject of Transposed Viscera —Dr. TAYLOR said that he noticed in the girl's case that the position of the cæcum and sigmoid flexure was unaltered.—Dr. ROBINSON said that he had examined the sister of the male patient and found a complete absence of the vagina, the uterus, and the ovaries —Mr. G. PERNET could not accept Dr. Taylor's theory of the cause and noted that neither patient was left-handed —Dr. PORTER said that he had seen a large number of twins but had never noticed this condition.—Dr. A. H. CLEMOW remarked that the cavities of the heart in the girl's case were not transposed.—Dr. TAYLOR, in reply, said that the children had not been examined. He admitted that his was only a theory, but it was the only one which would explain these cases.

Mr. H. CARRÉ SMITH showed two cases of Spastic Paraplegia (sisters), one aged 16 years and the other six years. The elder girl developed the disease at the age of five years and now had the characteristic gait and rigidity. The knee-jerks were exaggerated and ankle clonus was marked. She had incontinence and was also mentally deficient. The younger child developed symptoms as soon as she commenced to walk. The father and mother were first cousins and healthy. Between these children the mother had had seven other children, all born at the seventh month and all of whom died. She had also had three miscarriages. Instruments were not used. Mr. Smith added that there were no signs of congenital syphilis in either patient, but thought that this must be the cause.—A discussion followed in which Dr. TAYLOR, Dr. CROOKSHANK, Dr. TINDAL ATKINSON, Mr. G. PERNET, and Mr. C. B. KEETLEY took part, and in reply Mr. SMITH said that no nystagmus had been observed. He was treating the cases with iodide of potassium.

Mr. KEETLEY showed a New Method of Treatment in Disease of the Hip-joint. The patient, a girl, had had the disease for a long time. Mr. Keetley operated and removed the head of the femur and surface of the acetabulum. The skin around became infected with tuberculous ulceration, leaving a huge wound. A second operation became necessary and when removing the tuberculous material from the skin he opened up the joint again by means of a longitudinal and transverse incision and scraped out the joint. He then laid a number of Thiersch's grafts on the wound and some of these he put right into the joint. The result was very good, the joint closed up at once, and within a month the surface was healed, the grafts in the joint being pushed to the surface.—Mr. PATON thought that Mr. Keetley's method was very gratifying and successful, as it did away with all tubes.

Dr. P. S. ABRAHAM showed a case of Lichen Planus in a man, aged 40 years. The eruption practically covered the body—the pruritus was very severe. He was previously healthy but had suffered from carbuncles. He was being treated with arsenic.—Dr. DOBSON thought that arsenic was useless in these cases and advocated morphia and nerve sedatives.—Dr. A. WHITFIELD agreed that internal nerve sedative treatment was much more important than arsenic.—Dr. ABRAHAM, in reply, said that he was not at all a believer in arsenic in these cases, but that sometimes it was very successful. He also used morphia and thyroid gland.

Dr. J. B. BALL showed a case of Warty Growth just within the ala nasi in a female. It had existed for 12 months and was slightly ulcerated. The cause was doubtful. Lupus and rodent ulcer had been suggested, but he should remove the growth and examine it.—Dr. WHITFIELD thought that the growth was epithelial in nature, as the mucous membrane was not attacked.—Mr. PERNET thought that the case was one of rodent ulcer.—Dr. ABRAHAM also agreed that it was probably rodent ulcer.

Mr. DUNSTAN BREWER showed a microscopical specimen of the Lung of a Mouse showing bacillus pestis *in situ*.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

THE third ordinary meeting of this society was held on Dec. 19th, Mr. A. G. MILLER, the President, being in the chair. The meeting was devoted to clinical demonstrations.

Dr. R. MCKENZIE JOHNSTON presented a patient in order to elicit a diagnosis. The patient, a man, aged 24 years, had a large Growth in the Left Tonsil extending up to the middle line. He was perfectly healthy otherwise. About two months previously he began to suffer from slight and occasional dysphagia, fluid then regurgitating through the nose. He had no pain, but four months ago it was noticed that he spoke somewhat thickly. The growth was perfectly smooth and had no tendency to ulceration, though it bled rather freely on touching. Owing to the rapidity of its growth Dr. Johnston thought that it was a lympho-sarcoma.

Dr. BYROM BRAMWELL exhibited the following:—1. A case of Aneurysm of the Thoracic Aorta successfully treated by Iodide of Potassium. The case was important because Dr. Bramwell had never yet seen any such case so thoroughly cured. The patient was an old soldier, aged 68 years, who was discharged from the army when he was aged 28 years because of disease of the left elbow-joint. The arm was amputated through the upper third of the humerus. He then worked as a labourer until 24 years ago when he developed well-marked symptoms of thoracic aneurysm—e.g., shortness of breath, dysphagia, and pain. Under the care of Dr. G. W. Balfour in the Old Royal Infirmary and treated with iodide of potassium these symptoms were completely relieved. He then began hawking goods, walking from 10 to 20 miles daily and carrying a pack weighing from 20 to 40 lb. He kept at this work constantly for 24 years. A few months ago he began to suffer from pain in the chest, apparently shooting down the left arm, and from cough and expectoration, together with some changes in the lung (no tubercle bacilli were present). There was only a slight prominence, but a well-marked pulsation in the second left interspace. The dulness on percussion was not absolute, but diminished outwards from this centre. The second aortic sound was accentuated and there was a difference in the carotid pulses. The diagnosis made 24 years before had proved to be correct and Dr. Bramwell had never seen a patient with this disease living so long while doing such arduous work. The dysphagia which was present when first treated was, in Dr. Bramwell's experience, usually a near precursor of the end. 2. Three patients in whom great improvement had resulted from the Treatment by Coördinated Exercises by Fraenkel's Method. Such a treatment had not been employed to any extent in this country and had been brought under Dr. Bramwell's notice by his son, Dr. Edwin Bramwell. The first two cases were those of women who a month ago exhibited marked symptoms of tabes, not being able to walk without assistance from another person, but now both could walk fairly well and turn without difficulty. The third case occurred in a man who had been under observation for several years and had suffered from the ordinary typical manifestations of tabes, including gastric crises. He also had been under treatment for a month with a notable improvement. In many cases of locomotor ataxy this method of treatment produced very decided improvement.

Mr. H. ALEXIS THOMSON exhibited a boy, aged 15 years, showing the Result of Resection of the Middle Two-thirds of the Tibia for Central Abscess. Eight years previously the boy had suffered from osteomyelitis affecting the lower end of the femur on the left side and also the right tibia. He recovered perfectly from this except that the tibia was thickened and arched forwards. Eight months ago he presented himself again with all the characteristic symptoms of Brodie's abscess of the right tibia. The middle two-thirds of the bone were removed subperiosteally and the tibia re-formed itself well within three months. Specimens were shown.

Mr. J. SHAW MCLAREN showed:—1. Two cases of Psoas Abscess after Treatment by the Injection of Iodoform Emulsion. His method of treatment was to evacuate the abscess by puncture and then to introduce a quantity of 10 per cent. iodoform emulsion. The operation was remarkably simple and almost any practitioner could perform it at the patient's home. One successful case shown was that of a girl, aged 17 years, who had suffered from curvature in the lower part of the spine for years with a psoas abscess extending down to Poupart's ligament. Within six weeks of this treatment she was entirely cured. The second case occurred in a woman and in her case the abscess was enormous, extending down to the middle of the thigh; now, however, it had entirely gone. 2. A patient with Tuberculosis of the Left Wrist treated by iodoform emulsion injection. The lad had previously been twice operated upon for disease of the joint, but the condition had manifestly improved under this treatment along with the application of the congestive bandage. 3. A patient after complete Removal of the Tongue and Glands for cancer two years ago.

Mr. HAROLD J. STILES exhibited:—1. A young woman, a servant, after operation for Perforated Gastric Ulcer. She had previously shown slight symptoms of indigestion, but suddenly one morning after breakfast she was seized with intense pain. The operation was performed three and a half hours after the accident and the rupture was found to have taken place high up on the posterior aspect and close to the œsophageal opening. The lesser sac of the peritoneum retained the escaped contents of the stomach and they had not at the time of operation escaped into the general peritoneal cavity. 2. A girl showing Regeneration of Skin, the result of skin-grafting, after entire avulsion of the scalp. Much difficulty had at first been experienced in getting the grafts to grow and the best plan which Mr. Stiles had found was to lay on a graft about two inches square (after scraping off the granulations and arresting the bleeding), covering this with a sheet of perforated protective and finally a piece of sterile gauze smeared over with vaseline. The entire scalp was now restored with the exception of two or three tiny areas. 3. An infant three months after

Removal of a Large Occipital Meningocele 16½ inches in circumference. The tumour was larger than the child's head and sprang from a narrow opening in the bone just below the occipital protuberance. The pedicle measured five and a half inches in circumference. Mr. Stiles said that in order to prevent escape of cerebro-spinal fluid the cicatrix should be made very firmly and this he accomplished by making the skin flaps so large that they could be flatly approximated together and a double layer of sutures could then be passed through them. The specimen of meningocele was shown. 4. An infant, aged four months, after operation for Acute Intussusception. The tumour was very large and was operated on 23 hours subsequent to its formation Mr Stiles said that almost all such cases should be treated by operation as the method of attempted reduction by inflation was extremely unsatisfactory. The lower two-thirds of an intussusception were as a rule easily reduced by pushing the bowel from below upwards (after laparotomy), but the upper part was very difficult to reduce and could hardly be done by inflation alone. 5 A boy with Paralysis of the Gluteus Maximus Muscle which was the result, apparently, of acute anterior poliomyelitis.

Dr. Alexander Bruce and Professor Thomas Annandale showed a man suffering from Paralysis relieved by removal of the twelfth dorsal lamina. It was a complex case of alcoholic neuritis and injury to the spine in the region of the twelfth dorsal vertebra from a fall down a stair. At the operation a bony projection was found attached to the left lamina of the twelfth dorsal vertebra compressing the cord. This was removed and now his condition was improving, though as the injury happened more than a year ago a good deal of neuritis must have been set up. He had quite recovered from the alcoholic neuritis.

Dr. Norman Walker exhibited two patients.

Dr. Allan Jamieson demonstrated under the microscope the Structure of the Cervical Skin Tumours shown at the November meeting.

Mr. McLaren showed: (1) Recent Pott's Fracture; (2) Radiographs of Fractured Internal Condyle; and (3) Fracture of Astragalus with subgaloid luxation of the foot forwards.

Mr. Stiles showed: (1) A Portion (three and a half inches long) of a Hatpin removed from a Male Bladder by suprapubic cystotomy; (2) Brain with Abscesses secondary to Head Injury; and (3) Congenital Fatty Tumour from the Axilla of an Infant.

Dr. H. Harvey Littlejohn showed: (1) Brain from the patient in a case of Apoplexy in which there was partial recovery but suicide by throat-cutting six weeks later; (2) the Cut Throat from the above case; (3) Complete Rupture of the Small Intestine due to a simple fall; (4) Double Uterus; and (5) Acute Inflammation of the Stomach.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Indentations in the Skulls of the New-born.—Eclampsia.

A meeting of this society was held on Dec 12th, Dr. R. Milne Murray, the President, being in the chair.

Dr. N. T. Brewis showed (1) a Fibro-Cystic Tumour of the Broad Ligament; (2) a Uterus removed for Cancer of the Body; (3) a Uterus and Appendages with Ovarian Abscess and Pyosalpinx, resulting from a recent miscarriage; and (4) a Fibromyoma removed by Sub-peritoneal Hysterectomy.

Dr. F. W. N. Haultain exhibited (1) a Fibroid Uterus removed by Pan-hysterectomy; (2) a Superinvoluted Uterus affected with cancer of the cervix and removed by the vaginal route from a patient, aged 29 years; (3) an Extra-Uterine Gestation; and (4) an Omphalopagus Twin Monster, born dead at full time, and weighing 15 lb

Professor A. R. Simpson showed a Ruptured Ovarian Cystoma

Dr. G. Scott MacGregor showed a Uterus removed by Vaginal Hysterectomy from a patient, aged 26 years, for early cancer of the cervix.

Dr. G. F. Barbour Simpson showed a Ring Pessary which had been retained for 25 years in the vagina.

The President exhibited (1) a Dermoid Ovarian Tumour with other Ovary showing a recent Corpus Luteum; and (2) a Myoma of Rapid Growth removed by Hysterectomy.

Dr. Munro Kerr (Glasgow) read a paper on Spoon-shaped Indentations in the Skulls of the New-born, with illustrative cases, and a New Method of Treatment for the Immediate Relief of the Deformity. This subject had received very little attention in this country; in Germany it was little better; in France, however, it was very different. Ambrose Paré first referred to the deformity and numerous treatises had since appeared on the subject. Indentations of the fœtal skull might either be spoon- or furrow-shaped. The two varieties occurred with about equal frequency. They had, however, not the same significance, for although the conditions producing them were in the main the same the furrow-shaped variety was much less serious and seldom gave rise to much immediate trouble. Dr. Kerr, therefore, considered exclusively the spoon-shaped depressions. The injury, which was usually situated on one or other of the parietal or frontal bones in the neighbourhood of the anterior fontanelle, was by no means uncommon, especially in the city of Glasgow, where rickets was so prevalent among the lower classes and parturition was in consequence so frequently laborious. The accident occurred, with few exceptions, when there was a deformity of the maternal pelvis and generally in women with flat rachitic pelves. The extent of the deformity need not be extreme; most commonly it was just sufficient to cause a moderate degree of obstruction to the passage of the head. In the great majority of the reported cases delivery was completed by traction, either on the child's head by forceps or on the trunk in breech cases, or after turning Still, in a small proportion of cases labour ended spontaneously. Rosenski in 43 collected cases found spontaneous birth in only two cases. When deformity existed the indentation was usually caused by the head being pressed against the projecting sacral promontory. Occasionally the anterior pelvic wall, an undue prominence of the ilio-pectineal eminence, and still more rarely an osseous tumour of the bony canal might be the cause. Some had mentioned lateral deviation of the uterus, ankylosis of the coccyx, and tumours of the soft parts as causes. Defective ossification of the fœtal skull predisposed to the accident. Dr. Kerr in experiment found that he could produce depressions with the greatest ease and with very little pressure in some cases, but in others no indentation could be made even with considerable force. A prolapsed upper limb by narrowing the pelvis might produce a depression. In the majority of forceps cases the indentation was produced by pressure of the head on the promontory of the sacrum and not directly by injury from the blades of the forceps Occasionally two depressions might be found on the same skull, and the accident had occurred in even five successive births. The prognosis was not unfavourable; in most cases the indentations disappeared in a week or two and gave rise to no immediate symptoms or later ill effects. In a certain number the depressions resulted in a permanent deformity, and might produce no disturbance or they might give rise to minor nervous storms. Some cases terminated fatally, and in these the symptoms varied. There might be twitchings, convulsions, and paralysis, and quite evidently due to the indentations In other cases these symptoms might only appear at the end, but the children showed fretfulness, were disinclined to take the breast, and did not thrive. In another group the child was born asphyxiated, and unless the depression was speedily removed the child died despite all other attempts at resuscitation. Schroeder, out of 65 cases, found that 34 per cent. of the infants were stillborn, 15 per cent. subsequently died from the injury, and the rest remained alive, as far as he could find out. In treating the condition exhaust-pumps and cupping-glasses had been advocated or the application of an adhesive plaster and traction exerted on it. Trephining had been successfully performed for this condition. In a case recorded by Boissard there was a large depression on the left frontal bone with protrusion of the left eye. The case seemed hopeless as the heart's action was very feeble Boissard incised the scalp over the coronal suture, made a small opening through the suture, and passed a sound under the bone between it and the dura mater and pressed up the depression. The child immediately began to breathe and rapidly recovered. Panzani reported a similar case. Surgical interference could not always be immediately practised from lack of instruments, &c. Dr. Kerr had used the following treatment in three cases successfully. The fœtal bones were very resilient, and by experiment on stillborn infants he found that artificially produced depressions could be raised by firm antero-posterior compression of the head. On the living child the indentation came out with a jerk and with a sound as when a dent in a felt hat was removed. In one case the seriously impaired respiration was immediately relieved after the indentation was removed by this method.—Professor Simpson, Dr. D. Berry Hart, Dr. H. M. Church, Dr. James Ritchie, Dr. W. Fordyce, and the President made remarks on the paper.

Dr. Michael Dewar read a paper on a case of Eclampsia at the sixth month with successful labour at full time. The patient was a married primipara, aged 28 years, strong, well-developed, and with no neurotic personal or family history. During her pregnancy she suffered very little from morning sickness and passed the ordinary amount of urine daily; the bowels were constipated. She was very well until suddenly, without any warning, she was seized by a fit and had a succession of eight fits in an hour. In one attack, it was noticed, her face was drawn to the right side; then a long tonic convulsion occurred, succeeded by a series of strong, rapid clonic contractions involving the whole body; the attack lasted three minutes. The urine was drawn of by catheter and found to be free from albumin. Consciousness soon returned after the tenth fit, but she remained somewhat dazed. Next day her urine was plentiful and also non-albuminous. Bromide of potassium and chloral were administered continuously. Four days after the first attack she had a second series of convulsions, seven in number. This time the urine showed a trace of albumin. Three days later she had a third series of fits, three in number; the urine on the following day was found to be free from albumin. She gradually improved after this, though remaining confused in mind. Labour came on at full time and was quite normal and the child was quite healthy. The mother was now very well with the exception of a slightly defective memory; the urine was normal and non-albuminous. In his remarks on the case Dr. Dewar considered the question of the fits, whether they were really eclamptic, as some observers asserted that unless albuminuria was present the case was not one of eclampsia. Convulsions, with or without albuminuria, seemed to be equally dangerous to the mother and child. There were many cases of albuminuria in pregnancy in which no convulsions occurred. There was evidently some subtle condition, as yet unknown, ready under peripheral or other influence to determine whether eclampsia would occur or not. As regards treatment, morphia was contra-indicated as it interfered with the kidney function. Veratrum viride in this case caused intermittency of the pulse and had to be stopped. Saline injection must at first increase the heart tension, which was high enough in these cases. He believed in a little more of the expectant treatment, attending to the bowels and the bladder, with the administration of a bromide and chloral.—Professor Simpson, Dr. Haultain, Dr. S. Macvie, and the President took part in the discussion.

Society of Anæsthetists.—A meeting of this society was held on Dec. 7th, Dr. F. W. Silk, the President, being in the chair.—The secretary read a communication from Mr. Wilfred Sars giving particulars of a Recent Fatality under Nitrous Oxide Gas which occurred at the Great Northern Central Hospital and which had been fully reported in the medical journals.—Dr. H. Low and Dr. Dudley Buxton thought that nitrous oxide was always contra-indicated in cases in which there was any impediment of a progressive character involving the upper air-passages, for which cases Dr. Dudley Buxton recommended pure chloroform in preference to ether or any mixture.—Dr. Probyn-Williams related particulars of a somewhat similar case that had occurred at the London Hospital.—Dr. A. H. Cook remarked that in cases of obstructed respiration such as in adenoid growths he preferred the A.C.E. mixture and thought that the cases alluded to pointed to the desirability of promptly performing laryngotomy when the patient's life was found to be in jeopardy from œdema of the glottis.—The President thought that some additional cause of death than mere mechanical obstruction was to be sought in such cases and referred to the comparative frequency with which patients suffering from tonsillitis became faint during or after the administration of nitrous oxide.—Dr. Probyn-Williams then gave particulars of two fatal cases during the administration of an anæsthetic (one ether and one chloroform) in both of which it was shown at the post-mortem examination that the death was really due to a distinct ante-mortem blood-clot becoming detached from the veins and impacted in the right side of the heart.—Dr. Clapham, of the North-Eastern Hospital for Children, read notes of a very similar case occurring in a boy, ten years of age. It was noticeable that all three cases were more or less septic.—Dr. Dudley Buxton welcomed the reporting of these cases to the society and thought that they were important additions to their knowledge. He was of opinion that under certain circumstances the mere disturbance of the circulation which the inhalation of an anæsthetic always entailed, even apart from struggling, &c., would suffice to loosen an already formed clot, and he had seen a small aneurysm quite cured in this way.—Dr. Low also spoke and Dr. Probyn-Williams replied.—The President thanked Dr. Clapham for bringing the case before the society.

Glasgow Southern Medical Society.—A meeting of this society was held on Dec. 20th, Dr. William Watson, the President, being in the chair.—The adjourned discussion on the recent decision of the General Medical Council respecting the sale of drugs and poisons by unqualified drug assistants was continued. An interesting debate took place. In addition to other points brought under review it was shown that by an ordinary interpretation of the word "drugs" which occurs in the indictment any medical man would be held in the same way guilty should his unqualified drug assistant sell such simple articles as Epsom salts or cream of tartar. It was also pointed out that if any breach of the law had been committed the Pharmaceutical Society had power to enforce it in a different court under the Pharmacy Acts, and that the General Medical Council should not have acted as prosecutors. The discussion having been brought to a conclusion the following motions were proposed and adopted:—

1. That this society appoint a committee to draw up a representation to the General Medical Council on the points brought out in the discussion of the case of Dr. Thomson of Airdlie.

2. That the secretary of this society be instructed to call a meeting of the general medical practitioners of Glasgow and the West of Scotland at an early date for the consideration of the action of the General Medical Council in their recent decision regarding the sale of drugs and poisons by unqualified assistants.

3. That the Glasgow Southern Medical Society, believing the direct representation of the general medical practitioners of the United Kingdom on the General Medical Council to be inadequate, humbly petition the Medical Council to represent such inadequacy to Her Majesty's Privy Council in order that the medical practitioners of Glasgow and the West of Scotland may elect an additional representative.

Pathological Society of Manchester.—A meeting of this society was held on Dec. 12th, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. R. W. Marsden read a paper reviewing the subject of Gall-bladder Infection in Typhoid Fever and exhibited the gall-bladder from a case of typhoid fever. The specimen showed irregular inflammatory thickening of the walls with numerous small ulcerations in the mucous membrane, some of the ulcers being covered with small brownish necrotic patches. At the fundus there were two or three ulcers of larger size, whilst the largest occupied the tip of the fundus, and in the centre of it a perforation was present. Microscopical specimens from the same case were also exhibited. In the section of the wall of the gall-bladder localised newly-formed or inflammatory masses were seen in the connective tissue stroma and not having any apparent relation to the ulcerations. In the section of the liver were areas in which the liver cells had not received the staining fluid used and in which an accumulation of leucocytes had taken place, constituting patches of focal necrosis.—Dr. A. Donald showed: (1) A Bicornute Uterus which had been removed by abdominal hysterectomy immediately after labour on account of a double rupture; and (2) two specimens of Pregnancy Complicated by Fibroid Tumour. In both cases abdominal hysterectomy had been performed.—Dr. F. Villy showed Preparations of the Cardiac Muscle from patients dying from Diphtheria and briefly referred to the significance of the degeneration present.

Wigan Medical Society.—A meeting of this society was held on Dec. 13th, Dr. M. Benson presiding over a good attendance of members and visitors.—After the routine business a paper was read by Dr. T. Arthur Helme on Some Obstetric Topics under Present Discussion.—The paper was a very interesting one and led to a prolonged discussion, the following members taking part therein: Dr. Benson, Dr. R. P. White, Mr. M. McElligott, Dr. F. Rees, Mr. C. M. Brady, Mr. E. H. Monks, Mr. T. M. Angior, Mr. R. Tarbuck, Dr. W. S. Sinclair, and the honorary secretary.—A cordial vote of thanks was accorded to Dr. Helme, which he acknowledged.

FOLKESTONE MEDICAL SOCIETY.—A meeting of this society was held on Dec. 7th, Dr. W. J. Tyson, the President, being in the chair.—A deputation of four members was selected to meet the sanitary committee of the Town Council and to discuss a few questions about which the society is concerned.

Reviews and Notices of Books.

An American Text-book of Physiology by Several Authors Edited by WM. H. HOWELL, Ph.D., M.D., Professor of Physiology in the Johns Hopkins University, Baltimore, Maryland. Vol. I. Second edition, revised. Philadelphia: W. B. Saunders and Co. 1900. Pp. 598. Price 26s.

THE number and variety of the text-books of physiology that have been published during the last few years constitute in themselves an indication of the rapid advances that are constantly being made in this branch of knowledge, each author thinking that his predecessors have left something untold or dealt with various points in a manner on which he could improve. The volume before us seems to be one of the best of such text-books. It is written on the plan of collaboration, different subjects having been committed by the editor into the hands of experts. The editor states in the preface that the collaboration of several teachers in the preparation of an elementary text-book of physiology is unusual, the almost invariable rule heretofore having been for a single author to write the entire book. Of this there is no doubt, and Dr. Howell deserves the credit of being one of the first to select several accomplished physiologists to unite in producing a work that is thoroughly up to date and to resist the temptation of writing chapters that he was himself fully qualified to undertake The several chapters in the present volume with their authors are the General Introduction, Blood, Lymph, Secretion, Chemistry of Digestion, and Movements of the Alimentary and Urinary Systems, by Dr. Howell; Circulation, by Dr John G Curtis; the Innervation of the Heart, by Dr. W T. *Porter*; *Respiration and Animal Heat, by* Dr Edward T. Reichert; and the Chemistry of the Animal Body, by Dr. Graham Lusk.

In making a study of this work we must say at the outset that we approve of the mode in which the several subjects are presented to the reader. The exposition is clear, the arrangement is good, and the language is lucid and yet concise The subjects of the blood and circulation are very satisfactorily dealt with, the text including the most recent information and giving some points that are not often mentioned. Thus there is a paragraph on the globulicidal action of the serum in which it is stated that different kinds of serum show different degrees of globulicidal activity and that white as well as red corpuscles may be destroyed. *Dogs'* serum or human serum is strongly globulicidal to the blood of rabbits This is not due apparently to variations in the amounts of inorganic salts in solution, since the mere heating of the serum to 55° or 60° C. for a few minutes destroys the globulicidal action, though the other constituents of the serum, as the proteids, do not appear to undergo any alteration. Foreign serum injected into the veins of a living animal may exert a marked toxic effect that can hardly be explained by its globulicidal action, for the injection of no more than from 7 to 14 cubic centimetres of fresh dogs' serum will suffice to kill a rabbit; and then, again, serum is known to exert a similar destructive effect on bacteria, which is termed its *bactericidal* action. "These three effects of serum—globulicidal, toxic, and bactericidal—seem all to be destroyed at a temperature of from 55° to 60° C., and it is possible that they are all traceable to the existence in the blood of some proteid substance, an alexine which is present in small quantity and is different for each species of animal." Dr. Howell *considers that it has been satisfactorily* shown that in the adult the organ for the reproduction of the red corpuscles is the red marrow of bones. Here the erythroblasts are formed which multiply by karyokinesis, the daughter cells producing hæmoglobin in their cytoplasm, thus forming nucleated red corpuscles. The nuclei are subsequently lost either by disintegration or more probably by extrusion, and the newly formed non-nucleated red corpuscles are forced into the blood-stream.

Dr. Howell speaks guardedly on the cause or causes of the sounds of the heart, but he seems inclined to admit both a valvular and a muscular element. He mentions, but passes by without comment, the late Sir R. Quain's theory. *Dr. Howell seems* to doubt whether the dicrotic wave is a reflected wave from the periphery or whether it proceeds from the semilunar valves. We thought that it was very satisfactorily determined to be of central origin and to proceed centrifugally. Amidst all the details of the action of the heart and the characters of the circulation in the several orders of vessels that are here given we fail to find one point of applied physiology that is interesting to every practitioner—the circumstances that prevent a man from bleeding to death if he have the misfortune to inflict upon himself a superficial flesh wound. Dr. Howell deals sensibly with doubtful and disputed questions. Thus in regard to the formation of lymph he points out that two divergent views are held in regard to it. According to some all the facts known respecting the composition of lymph may be satisfactorily explained if we suppose that this liquid is formed from blood plasma by the combined action of the physical processes of filtration, diffusion, and osmosis. According to others it is believed that in addition to these actions it is necessary to assume an active secretory process on the part of the endothelial cells composing the capillary walls. Dr. Howell then gives an excellent summary of the numerous and important experiments of Heidenhain and Starling, and concludes by adopting, provisionally at least, the mechanical theory.

If we turn to such a subject as that of the spleen and read what Dr. Howell has to say upon the *functions of that* organ, for all details of its structure are rigorously excluded, we shall find that the theories of its purpose in the economy which are in Dr Howell's opinion most worthy of being considered, though all are unsatisfactory, are that it is a seat of origin for the red corpuscles of the blood; that it is an organ in which the destruction of the red corpuscles takes place; that it is a place where uric acid is generated; and, lastly, that an enzyme is here formed which, carried by the blood to the pancreas, converts the trypsogen contained in the pancreatic cells into trypsin Of this last theory, propounded by Schiff and supported by Hensen, he only remarks that the experimental evidence adduced by these two observers has not been *confirmed by others* We are disposed to think that the conclusions of Schiff and Hensen from their experiments rest on a sounder basis than do those of their opponents.

If we had to find any fault with the work, it would be that such a subject as the kidney and its secretion are considered under several separate heads For instance, under the head of the urinary organs the terminal capsules of the kidney tubules with their blood-supply are first described, a paragraph on the composition of the urine succeeds, which is followed by an account of the secretion of urine, the elimination of urea and related bodies, the secretion of the water and the salts, and the blood flow through the kidneys; but the student who wishes to know the composition of the urinary constituents must look for it under the account of the Chemistry of the Animal Body, where full and accurate details will be found, and micturition under yet another heading—the Movements of the Alimentary Canal, Bladder, and Urethra. The same remarks apply to the account of the salivary secretion, which leads to some unnecessary repetition. Illustrations are sparingly introduced. The work is one on which full reliance can be placed as representing the present state of physiological knowledge.

LIBRARY TABLE.

The Physiological Feeding of Infants. By ERIC PRITCHARD, M.A., M.D. Oxon. London: The Scientific Press, Limited 1900. Pp. 39. Price 1*s*.—Physicians in charge of the out-patient children's department are aware that a large proportion of the little patients are brought under their notice owing to defective feeding, generally due to the ignorance of those under whose care they happen to be. The mothers or guardians are frequently quite unaware that the method of feeding is at fault, and some of them resent the "advice" given to them, having come to the hospital for "a bottle of medicine," which they believe will cure all disorders. The majority, no doubt, thankfully listen to the directions given to them and carry them out to the best of their ability. The physician, nevertheless, is at a disadvantage in giving such instructions. The physiological feeding of infants is by no means an easy matter (supposing that circumstances prevent them from being breast-fed), and in cases of disordered stomachs innumerable difficulties arise. In the pamphlet now before us Dr. Pritchard has made an attempt to lay down certain directions whereby cow's milk can be so modified as to be applicable to the various disordered infantile digestions which are so frequently met with in private and hospital practice. We can congratulate the author on the success of his endeavours. Suggestions are made in many medical text-books, especially in those by American authors, as to the method of altering the percentage of fat, proteid, and sugar which should be given in infants' food; but as a rule the prescriptions are so complicated as to be most difficult to follow. Dr. Pritchard, however, has devised tables giving recipes for preparing milk mixtures of various percentage composition; the quantities, however, are given in ounces and drachms, so that there would be no difficulty in preparing the food. This is an admirable plan and one that will be generally appreciated. A "Physiological Nursery Chart" is also issued, containing a table for registering the weight of the child for many months, a table for preparing modified milk for a healthy infant of average weight during the successive stages of its life from one day to one year, and numerous "directions" and "aphorisms" which cannot fail to be of the greatest value to nurses and mothers. The actual chart is printed on a large card and the specimen before us gives a view of the progress of a child up to the age of two years. The abscissæ of the chart answering to the dates in an ordinary temperature chart are at the top weeks, at the bottom months, so that when the chart has been kept in weeks, beginning from the left hand bottom corner proceeding towards the right, it can be continued by months, starting from the right hand bottom corner proceeding towards the left. The ordinates answering to degrees of the thermometer in a temperature chart show degrees of weight increasing by quarter pounds.

Golden Rules of Skin Practice. By DAVID WALSH, M.D. Edin., Honorary Physician to the Western Skin Hospital. Golden Rules Series No. VIII. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent and Co., Limited. 16mo. 1900. Pp. 102. Price 1*s*.—This little book is one of a series, and therefore has been written to correspond with the other members of that series. It contains many useful hints for treatment and many general "aphorisms" relating to dermatology. The symptomatology and diagnosis are less fully described. The teaching is sound on the whole. We would, however, demur to the following statements: "Incise both boils and carbuncles early. The old-fashioned heroic crucial incisions are nowadays abandoned." It is true that a mere crucial incision is not now used for a carbuncle, but the best treatment is now even more "heroic," for the whole carbuncle is scraped away with a sharp spoon and the denuded surface is swabbed with a strong antiseptic. In the treatment of lupus nothing is said of the value of light, although the use of the Roentgen rays is mentioned.

Minor Surgery and Bandaging. By HENRY R. WHARTON, M.D., Demonstrator of Surgery in the University of Pennsylvania, Surgeon to the Presbyterian Hospital, &c. Fourth edition, thoroughly revised and enlarged. With 50 illustrations. London: Rebman, Limited. 1899. Pp. 594. Price 14*s*. net.—The title of this work does not accurately denote the subjects dealt with, for in addition to those usually comprehended in the title "Minor Surgery and Bandaging," we find included a fairly full account of nearly all the operations performed on the body, even gastro-enterostomy being described. These descriptions, however, are accurate but brief. The chapter on Bandaging is very good, and rather more forms are described than are usually met with in most English text-books. The chapter on Minor Surgery is complete and deals with antisepsis and asepsis, dressings, anæsthetics, trusses, catheters, methods of intestinal anastomosis, treatment of hæmorrhage, and so on. Chapters on fractures, dislocations, and operations are given, and are followed by chapters on amputations, excisions, and special operations. The book is carefully written and should prove very useful to a student of surgery or a house surgeon, and would often be found of value to those in practice. A few slips occur here and there which might be corrected in a subsequent edition.

A Manual of Jail Hygiene for the Use of Medical Subordinates. By Major W. J. BUCHANAN, B.A., M.B., B.Ch., D.S.M., Indian Medical Service, Superintendent, Central Jail, Bhagalpur. Second edition. Calcutta: Bengal Secretarial Press. 1900. Pp. 135. Price Indian Rs. 3; English, 4*s*.—We called attention to the first edition of this very useful little book designed for the information of medical subordinates in an annotation in THE LANCET of June 11th, 1898 (p. 1631), and in welcoming it we said that the subordinate should by its aid not only be able to carry out the orders of the medical officer but to know why those orders were given. We are glad to find that our estimate of this handy little volume has since been ratified by its success and the appearance of a second edition. It has, we understand, been officially adopted in the prisons of Bengal, Bombay, Punjab, Burma, Assam, and the Central Provinces of India. The object and intention which the author had in view in writing the book were excellent and calculated to meet a recognised want, and he has carried them out in a practical and useful way. The progress which has taken place, even in the short interval which has elapsed since its first appearance in January, 1898, has made it necessary to revise some chapters and to alter, and add to, others. The mosquito-malaria theory is simply and intelligently expounded, together with the new methods proposed for an attempted extermination of the mosquito—which probably have a better chance of being carried out in jails than outside them. Additions have also been made to the chapters on ventilation, scurvy, and dysentery, and an appendix on "How to Give Chloroform," by Lieutenant-Colonel E. Lawrie, I.M.S., has been added. The book, taken as a whole, supplies in a small compass a great deal of practical information set forth in a simple, intelligible style.

Wounds in the Rain. By STEPHEN CRANE. London: Methuen and Co. 1900. Pp. 347. Price 6*s.*—This collection of stories by the late Mr. Stephen Crane is concerned with the Spanish-American War of 1898. The stories are written with all the startling and grim realism which the "Red Badge of Courage" taught us to expect from the writer. Anybody who wants to understand the sort of thing our men have been enduring in South Africa will get a clear idea from reading this book, more especially the chapter entitled "Marines Signalling under Fire at Guantanamo." Take this passage: "The noise; the impenetrable darkness; the knowledge from the sound of the bullets that the enemy was on three sides of the camp; the infrequent bloody stumbling and death of some man with whom, perhaps, one had messed two hours previous; the weariness of the body, and the still more terrible weariness of the mind at the endlessness of the thing, made it wonderful that at least some of the men did not come out of it with their nerves hopelessly in shreds." If this is not the real thing, it should be.

JOURNALS.

The *Practitioner* in its December number provides rather a smaller amount of useful reading than is usually to be found in this periodical. The most important communication, in point of length at any rate, and probably also from other considerations, is a valuable article from the pen of Dr. William Hunter on Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Neuritis," and Other Septic Conditions. There can be no doubt that, as Dr. Hunter insists, the condition of the mouth generally receives too little attention from the medical man. Beyond an inspection of the tongue and fauces the general practitioner is not wont to bestow much care upon oral examination—at any rate, if the nature of the case does not at once point to the mouth as a seat of the original disease. The gums and the sockets of the teeth, however, are quite a sufficiently spacious field for serious septic influences, and it is in this way, as Dr. Hunter shows, as well as by the purely mechanical effects causing inefficient masticatory power, that the diseases of the teeth or of the tissues in their neighbourhood may play a very important and entirely unsuspected part in the production of serious disorder. Dr. Hunter's writings on this matter render valuable service by provoking more detailed routine examination of patients' mouths, although some of the remote effects which he traces to oral sepsis must, we think, be more fully proved to own this specific origin before their connexion with oral sepsis as a cause can be admitted with perfect freedom. A clinical lecture on Supra-pubic Cystotomy by Mr. Alfred Willett and a clinical demonstration on the Anatomy of the Spinal Cord by Dr. Howard Tooth are the other original articles of the number. Mr. Willett details some instructive cases. He is sceptical as to the value in diagnosis of the cystoscope, and we believe that most surgeons will agree with him that increasing familiarity with the use of this instrument does not afford the advantages that were looked for. In the Roentgen rays, too, Mr. Willett fears that surgery of the bladder will find no aids to diagnosis and we are not aware of cases that controvert his opinion. The "Medico-literary Causerie" deals with "Poisoners, Old and New," and is entertaining if somewhat lurid reading. A novelist of sensation hard put to it for a good story might very profitably consult the pages of this department of the *Practitioner*. We are comforted in reading it to reflect that the methods of analytical chemistry are nowadays so much more effective and far-reaching than they were when the poisoners of the seventeenth century flourished. Under the heading Public Health there is a very instructive account of clinical experiments carried out by M. Grancher in the Hôpital de la Rue de Sèvres at Paris to prevent the introduction and spread of infectious diseases among children in hospital. The methods employed are based upon the theory that infection is conveyed from patient to patient by direct contact or by indirect contact by means of the attendants—viz., nurses, students, and physicians. The infant patient is isolated in a sort of box and removed from the ward, and a strict *régime* of antisepsis and clothing is adopted by attendants who are brought into contact. The measures appear to be highly successful, and we recommend the detailed account of them to the perusal of our readers. The "Review of Medical Sciences" deals with bacterial and electrical therapeutics, with midwifery, and with dental surgery, the article upon the last subject touching on ground more thoroughly worked out in the writings of Dr. William Hunter to which we have already referred.

ASYLUM REPORTS.

Roxburgh, Berwick, and Selkirk District Asylum (Report for the Year ending May 15th, 1900).—The average number of patients resident in the asylum was 292 and comprised 134 males and 158 females. During the year 60 patients were admitted, of whom 33 were males and 27 were females. Of these, 15—viz., five males and 10 females—were not first admissions. Dr. J. Carlyle Johnstone, the medical superintendent, states in his report that owing to want of accommodation all private patients are now refused admission, except such cases as cannot possibly be provided for elsewhere. Among the cases admitted hereditary predisposition to mental disorder was ascertained to exist in 40 per cent., while suicidal tendencies were present in 37 per cent. Indeed, half of the patients with suicidal tendencies had made serious attempts to terminate their lives before admission to the asylum. 50 per cent. of the admissions suffered from some form or other of serious bodily disease. 11 patients were the subject of heart disease, five had phthisis, five had epilepsy, while eight patients were over 70 years of age on admission. "In only a small percentage of the admissions was there any prospect of recovery." During the year 18 patients were discharged as recovered, or 6 1 per cent. of the average number resident. The deaths during the year amounted to 25, or 8 5 per cent. as calculated on the same basis. Of the deaths one was due to rupture of the aorta, four to cardiac disease, five to influenza, five to phthisis, one to suicide by hanging, and one to suicide by taking carbolic acid. A severe epidemic of influenza visited the asylum in January and February, 1900; 30 per cent. of the patients and 40 per cent. of the staff were attacked, the latter making good recoveries. The necessity of increasing the accommodation for male patients is becoming every year more apparent, the present condition of things—viz., the absence of such accommodation—being "productive of much anxiety and unpleasantness." The asylum committee state in their report that the expenditure for the past year upon the asylum buildings, furniture, and the like amounted to £3983 5*s.* The statement of garden receipts and expenditure shows a net profit on the year of £115 12*s.* The Commissioner in Lunacy states in his report that "a larger and better equipped hospital section for male patients is much required, as the present male sick-room accommodation is both inadequate and unsuitable." The number of attendants and servants who have been engaged during the year is 13, the number who resigned is seven, and the number dismissed is five. The patients bear evidence of being well cared for, and the books and registers were examined and found to be regularly and accurately kept.

MUNICIPAL CONTEST IN GATESHEAD.—The election for the seat on the Gateshead Council rendered vacant by the death of the ex-Mayor took place before Christmas. There were four candidates and the seat was gained by Dr Alfred Cox, Cotfield House, Bensham.

THE LANCET.

LONDON: SATURDAY, DECEMBER 29, 1900.

THE ANNUS MEDICUS 1900.

MEDICINE AND THERAPEUTICS.

AMONGST the many diseases which have been particularly studied during the past year two stand out more prominently than the others owing to the number of observers who have been at work in investigating their origin, mode of spread, and possible prophylaxis—these two maladies are malaria and plague.

Malaria.

Nearly six years ago Dr. PATRICK MANSON brought forward the theory that a certain species of mosquito is the carrier of the malarial parasite. This suggestion has passed the stage of surmise and it may now be considered as a fact. The investigations of Dr. PATRICK MANSON, Professor CELLI, Professor GRASSI, Professor KOCH, Professor BASTIANELLI, Professor BIGNAMI, Major R ROSS, I M S., and others have proved beyond doubt that malaria is conveyed and spread by means of certain species of mosquito, and that the essential link in the life-cycle of the parasite—the means by which its existence is assured from year to year, in Italy at least—is malarial man. The period of the year at which malaria is most prevalent corresponds to the times at which the mosquitoes are most numerous. Older observers had noted that malaria was most likely to be contracted about sunset and at night. The anopheles lies hidden by day and pursues its search for food at night. Again, the old observers were aware that the "miasm" was often very limited and did not extend to any great elevation. Naturalists know that the mosquito does not fly far from its birthplace or mount high in the air. The various forms of the malaria parasite have been demonstrated in the bodies of the anopheles. An experimental proof of this theory was established by Mr. P. THURBURN MANSON, who submitted himself to be bitten by some mosquitoes of this species which had been forwarded to England, with the result that he became infected with an attack of tertian fever. Experiments equally important were carried out by Dr. L. SAMBON and Dr. G. C. LOW, Signor TERZI, and two Italian servants in the Roman Campagna at a spot known to be intensely malarial. By taking every precaution against the bite of the mosquitoes they remained entirely free from infection, in marked contrast to their neighbours, who were either ill with fever or had suffered malarial attacks. Most of the investigations hitherto carried out have been confined to the malarious districts of Italy. Whether the same results will be obtained in other parts of the world remains to be seen. In many regions in which malaria is prevalent it is probable that equally satisfactory results will be arrived at. It has been shown that if due precautions are taken a great degree of protection can be obtained. The importance of such knowledge can scarcely be over-rated. It is possible, however, that in some districts we have to do with a different disease to the "malaria" that is found in Italy, and that we must seek some other means of its spread than in the anopheles. Interesting experiences have also been related by Professor ANGELO CELLI as the results of experiments carried out in Latium.

Plague.

Plague has appeared in many parts of the world during the year, and thus additional importance was attached to the report of the Indian Plague Commission, especially with that part which deals with the value of Mr. HAFFKINE'S system of preventive inoculation. The conclusions at which the Commissioners arrived are briefly that inoculation sensibly diminishes the incidence of attacks and the case-mortality in those persons who have been inoculated. The inoculation, however, does not appear to confer any great degree of protection within the first few days after the operation has been performed, though it ultimately confers protection which lasts for a number of weeks—possibly for months. The varying strength of the vaccine employed apparently had no great effects upon the results hitherto obtained, and the true value of Mr. HAFFKINE'S method will probably not be thoroughly tested until after an accurate method of standardisation has been devised. In the report of the Commissioners the method of preparing the vaccine was fully discussed, but it is obvious that much yet remains to be done before the practice of inoculation with a fluid of this nature will fulfil all the conditions which sound scientific reasoning rightly demands of it. For the present—and this in itself is no small achievement—the method may justly claim to be a practical success and very nearly, if not quite, to attain to the high ideal of a certain and safe prophylaxis against one of the most deadly of all diseases. Time will doubtless remedy existing defects, and it is regrettable that the members of the Commission contented themselves with merely pointing out the imperfections and the necessity for overcoming them, and did not, with some minor exceptions, make any definite suggestions or recommendations as to the manner in which they should be overcome.

On August 27th and 28th general currency was given to a disquieting report that cases of suspected plague had occurred in Glasgow. The confirmation of the clinical diagnosis was soon forthcoming, and the country was then made aware of the unwelcome fact that after an absence of more than 200 years plague had once more obtained a certain amount of foothold in Great Britain. The original cases of imported plague could not be traced, but as soon as the diagnosis was established the whole forces of resistance at the disposal of the municipality of a great city, organised by one of the best public health departments which we possess, were at once brought into action. The procedure adopted—prompt hospital isolation, medical house-to-house visitation, formation of "cleansing areas," search (with the aid of bacteriology) for cases bearing suspicious similarity to plague, observation of "contacts," along with other administrative measures—soon had a marked effect, and the outbreak was speedily brought under control. A more extensive outbreak of the disease occurred in Sydney, Australia. The first case appeared on Jan. 27th, and up to July 28th there had been 302 cases and 102 deaths. During the whole of July, however, only six cases were reported, and for the week ending July 28th no fresh cases were notified although one of the patients in the hospital died.

The occurrence of the above outbreaks lent additional interest to the Harben Lectures delivered at the Royal Institute of Public Health by Professor A. CALMETTE, Director of the Pasteur Institute at Lille. In the course of these instructive lectures Professor CALMETTE remarked that it was now impossible to deny that the use of anti-plague serum as a preventive measure had been proved to be an excellent means of preventing propagation of plague in an affected centre, as by its means persons exposed to the contagion would be rendered absolutely and immediately immune. Unfortunately the immunity thus obtained was of short duration, and it was therefore necessary during an epidemic to repeat the injection every week The differences in the results thus obtained by Professor CALMETTE and those produced by Mr. HAFFKINE'S method are remarkable. Professor CALMETTE, indeed, alluded to the latter, but remarked that "this method was, however, open to some objection."

Anti-typhoid Inoculations.

The success of anti-typhoid inoculations is unfortunately by no means insured, and we must await the official returns from South Africa before arriving at any conclusion on the subject In the early part of the year Professor A. E WRIGHT, of the Army Medical School, Netley, published a paper on the Results which have been obtained by the Anti-typhoid Inoculations His statistics, however, did not include a large number of cases, and although the results might be characterised as encouraging, yet a far larger number of cases will have to be analysed before any decision is arrived at. The experience of our troops in South Africa has been the severest possible test of the value of the inoculations, and the opinions of the medical officers who have had only too many opportunities of observing how far the inoculations protect men from attacks of typhoid fever are universally awaited with the greatest interest and anxiety.

Epidemic Diarrhœa.

The subject of epidemic diarrhœa has been brought prominently before the medical profession during the past year. Dr. F. J. WALDO chose it for his Milroy Lectures. Epidemic diarrhœa—to choose one of its many synonyms—is one of the chief causes of the vast infantile mortality which has hitherto eluded the control of the public health reformer. Its etiology has not been definitely established. Dr. WALDO, from the analysis of a vast array of statistics, arrived at the conclusion that diarrhœal diseases are first and foremost the result of strictly local conditions; another suggestive feature in the history of the malady is the fact of its vastly greater incidence upon hand fed as compared with *breast-fed* infants Dr. WALDO suggests that epidemic diarrhœa is probably due in no small measure to the pollution of street-dust by horse dung. This theory would account for the disease being more prevalent in towns and amongst hand-fed children, since milk, which forms the staple article of infantile diet, is freely exposed to invasion by town dust, both in the shop of the retailer and in the larder or cupboard of the consumer. In connexion with this same subject the Home Counties Branch of the Incorporated Society of Medical Officers of Health made a sound request when they asked the Royal College of Physicians of London to appoint a committee to deal with the question of nomenclature in connexion with the certification and classification of "diarrhœa deaths." This request was acceded to and there is now an official name for the disease.[1]

The Open-air Treatment of Tuberculosis.

Many observers have reported on the treatment of pulmonary tuberculosis by the "open-air" method. This therapeutical measure seems to meet with increasing favour, and numerous sanatoria for the reception of phthisical patients are being built in different parts of the country that offer satisfactory sites in reference to exposure and soil.

Yellow Fever.

An interesting report on yellow fever was issued by Dr. WASDIN and Dr. H. D. GIDDINGS, of the Marine Hospital Service, Washington. They were deputed to study the etiology of yellow fever with special reference to Professor SANARELLI'S claim to the discovery of the specific bacillus of that disease. They came to the conclusion that there can be no doubt that the bacillus icteroides is the causal agent of yellow fever and they also are of opinion that infection takes place by the respiratory tract and not, as has generally been held, by the alimentary canal Other experiments of the Commission proved that the bacillus icteroides is very susceptible to the action of bactericidal agents.

The Purity of Glycerinated Vaccine Lymphs.

During the year we published a report of a Special Commission which we appointed to investigate the purity of various glycerinated calf vaccine lymphs at present in use. The general result of the inquiry, which was based on the application of the bacteriological test employed on several occasions and to different samples of the various commercial "lymphs," was the gratifying one that as regards their purity—i.e., freedom from harmful bacteria—very many of these samples were good. About half the samples were above the standard of the lymph supplied by the Local Government Board.

Rabies.

Professor J. ROSE BRADFORD in delivering two lectures on rabies brought forward many valuable facts in relation to that disease, referring more especially to its nature, symptoms, and diagnosis. His remarks on incubation, though brief, were full of interest He observed that most authorities are agreed that in man the incubation period lies between 20 days as a minimum and 60 days as a maximum, and that it is rare after three months and very rare, if not unknown, after six months. In cases which have been recorded after as long a period as 18 months the time has probably been reckoned on an erroneous basis

"The Fourth Disease."

In publishing a paper under the title of "On the Confusion of Two Different Diseases under the name of Rubella (Rose-rash)" Dr. CLEMENT DUKES has done good service to the profession, and indirectly to the public. To the mind of many observers Dr. DUKES has shown conclusively that there exists a disease which so nearly resembles scarlet fever as to have been frequently mistaken for it even when the opportunity has occurred of observing a multiplicity of cases. Whether this affection is specifically distinct, and not a form of German measles as is currently believed, is a point concerning which for the present judgment must be suspended. It is sufficient to say that Dr. DUKES made out a strong case for his theory. Future observations should determine the truth.

The Bacteriology of Scarlet Fever.

Further investigations have been made as to the bacteriology of scarlet fever by Dr. CLASS; and although it cannot be said to be proved absolutely that the diplococcus discovered by that observer is the specific germ of scarlet fever much evidence points in this direction. The streptococcus recently described by Professor ADOLF BAGINSKY and Professor PAUL SOMMERFELD as constantly present in the throat secretions and blood of patients suffering from scarlet fever may possibly be the same microbe as that discovered by Dr. CLASS, but the last named has pushed his investigations much further than have the German observers.

Scurvy.

Contributions on scurvy expressing rather conflicting views have been published by Mr. F. G. JACKSON and Dr. VAUGHAN HARLEY, Staff Surgeon W. E HOME, R N., and Professor WRIGHT of Netley, the latter maintaining that scurvy is a condition of acid intoxication very similar to the acid intoxication which can be experimentally produced in herbivora by the injection of a surplus of mineral acids.

Diabetes.

Useful and interesting work has been accomplished by Dr. F. W. PAVY and Dr. R. SAUNDBY on diabetes. Dr. PAVY dealt more particularly with the disease in its varied manifestations under the heading "Differentiation in Diabetes," in a paper read at the Thirteenth International Medical Congress held in Paris on Fundamental Points connected with the Pathology of Diabetes Mellitus. Dr. SAUNDBY, in a paper read before the Gloucestershire Branch of the British Medical Association at Cheltenham, referred more especially to the treatment of the disease, laying stress on the necessity of frequent examination of the urine in order to obtain information as to the quantity of carbohydrate food that the patient might advantageously take.

Lectures at the Colleges and Societies.

The various official lectures delivered during the year have been of the greatest interest. Dr. P. HORTON-SMITH delivered the Goulstonian Lectures before the Royal College of Physicians of London, taking as his subject the Typhoid Bacillus and Typhoid Fever. He discussed the various forms of microbes which might be mistaken for the pathogenic micro-organism and the different tests which have been prepared to distinguish them, and also showed a desire to reform our present classification of the disease.

The Lumleian Lecturer at the same College was Dr. W. B. CHEADLE who selected as his theme Some Cirrhoses of the Liver. His remarks on prognosis and treatment were particularly noteworthy.

The Croonian Lectures were delivered by Dr. F. W. MOTT, the subject being the Degeneration of the Neuron. The amount of matter condensed into these lectures was immense and well illustrated the extent of the change in our conceptions involved in the new doctrine of the neuron and also indicated that at the present time research is only laying the foundations on which the superstructure of knowledge must be built.

The Bradshaw Lecturer at the Royal College of Physicians of London was Dr. ARCHIBALD E. GARROD. His investigations on the Urinary Pigments in their Pathological Aspects have been deep and thorough and he proved that in certain cases the examination of the colouring matters of the urine may afford information of real diagnostic value which is not readily obtained in other ways.

Dr. NORMAN MOORE'S Hunterian Lecture, delivered before the Hunterian Society, on the Clinical Study of Heart Disease, contained numerous practical points of great value in clinical work, whilst Dr. R. MAGUIRE in the Harveian Lectures delivered before the Harveian Society, dealt with the principal points in the prognosis and treatment of Pulmonary Tuberculosis, the experiments which he had made upon animals and upon himself as to the effects of remedies administered intravenously being especially noteworthy.

The Hygienic Treatment of Tuberculous Diseases.

In reviewing treatment during the year 1900 attention may justly be directed first to the development of those means which claimed our chief attention in the preceding year. The hygienic treatment of tuberculous disease in its various forms has passed from the phase of controversy and ardent partisanship to that of definite trial on our own soil, and important conclusions have already been arrived at, both as to the best means of carrying out the method and as to the particular types of case which may be expected to respond satisfactorily or otherwise. Whatever may be finally settled by a comparison of results in regard to the relative value of different climatic conditions it has been pretty well established that the essentials of open-air treatment are at hand in most districts of Great Britain and Ireland. The physical conditions which offer the greatest difficulties to the practical therapeutist and are the most prejudicial in recent experience to the patients are heat and wind, and these are not more prevalent here than in most parts of the continent. Among the types of case regarded as unfavourable for a somewhat rigorous course of treatment, in which exposure and over-eating constitute the most prominent factors, are chronic forms and those complicated with catarrh of the bronchial or gastric mucous membrane. Besides these, acute cases and such as are attended with complications do better by postponing the course of hygienic treatment till the more active manifestations have subsided. It has been found that many forms of tuberculous disease other than phthisis, particularly those affecting the skin, bones, joints, and serous membranes, may be beneficially influenced by open-air treatment, and the same may be said of many general diseases such as anæmia, cachexia of various kinds, and even the acute fevers and functional nervous disorders; the feeling of well-being, increased appetite, and improved sleep resulting from systematic exposure reacting favourably on all these conditions. There is no doubt that a well-organised institution under a firm and judicious chief affords many of the advantages of foreign travel and residence without the vicissitudes, defective dietary, fatigue, absence of good continuous medical advice and supervision, and separation from friends which detract so much from this manner of treating invalids. The apprehension of the sick lest they should be ill, or perhaps die, far from home which has deterred many from trying the effect of a sea-voyage or foreign residence is removed by the institution of sanatoria at home.

The Use of Gelatin Solution to Increase the Coagulability of the Blood.

Gelatin solution injected into the subcutaneous tissue or administered by the mouth or rectum has been recommended as increasing the coagulability of the blood. The preparation employed consists of 1·5 per cent. gelatin in 0 7 per cent. solution of sodium chloride, of which as much as 250 grammes may be employed at one time, the injection being repeated at intervals of a week in cases of aneurysm for from 12 to 18 weeks. PINSUTI of Rome prefers a 30 per cent. solution with 2 or 3 per cent. of carbolic acid injected deeply in three-gramme doses, as being less painful. LANCEREAUX and PAULESCO report favourably of the method in some cases of aneurysm, but owing to the difficulty of determining whether these are sacculated or diffuse before applying the remedy great difference of opinion has been expressed as to its value. In some instances it has proved ineffectual, or actually injurious by extension or displacement of the clot. This objection has not been raised against its use in cases of spontaneous hæmorrhage such as occur in various blood diseases, nor in those instances in which it has been employed for internal hæmorrhage from ruptured vessels out of the reach of surgical interference. As a topical remedy also in cases of epistaxis, gastric ulcer, and uterine hæmorrhage gelatin solution, has been employed with greater efficacy and less risk. The solution, of course, needs to be carefully sterilised and judiciously applied, but there is a wide field in which such an agent might prove of great value and even the only available resource, besides rendering possible by its preliminary adoption operations which could not otherwise be undertaken, as in cases of hæmophilia.

Operative Measures in Medical Cases.

In the development of operative interference in medical cases the value of laparotomy in tuberculous peritonitis has been established. Recoveries have been recorded both in instances of doubtful diagnosis and after exploratory incisions, where the tuberculous nodules have been recognised and the patients have subsequently recovered, not merely from the operation, but from the constitutional disease. Following upon these a number of cases have been intentionally explored with advantage statistically as compared with those treated on simple medical lines. The ascitic form is that which derives the greatest benefit, but the dry adhesive and the ulcerative suppurating forms also do well. The dry ulcerative and the miliary forms of tuberculous peritonitis do not lend themselves to treatment by laparotomy, and absolute contra-indications to the operation are found in advanced pulmonary tuberculosis, intestinal tuberculosis, and pronounced cachexia. On the other hand, absolute indications in favour of operation are intestinal obstruction or perforation and suppuration. As a less severe measure in the same direction M. BAYLAC at the International Congress of Medicine proposed lavage of the peritoneal cavity with sterilised water at 45°C. Eight cases so treated resulted in five recoveries, while in three others there was only temporary improvement, these having been previously operated upon. In acquired hydrocephalus following meningitis Dr. GROSZ[2] punctured the lateral ventricles through the anterior fontanelle, removing 40 cubic centimetres of fluid from the right and 70 cubic centimetres from the left with recovery of the patient and subsidence of the symptoms.

Drugs.

Among old drugs which have been applied in new directions or in modified forms may be mentioned Dr. BOURGEON'S employment of calomel in daily amounts of from three to six grains as a diuretic in heart disease irrespectively of the presence of dropsy and when there is no albuminuria or diarrhœa. Croton oil in doses of from one-eighth to one-sixth of a minim in a pill with liquorice makes an effective purgative, rarely rejected even in irritable conditions of the stomach, and promoting both peristalsis and secretion, thereby softening and loosening masses which in the pouches of the colon may be retained for weeks undisturbed by the ordinary hydragogue purgatives. This remedy acts efficiently in dilatation and atony of the stomach where other remedies are not absorbed, and proves of great service in stercoræmia, which is at the root of many obstinate functional conditions, such as asthma, migraine, epilepsy, dyspepsia, and the effects of high arterial tension.

Atropine in doses of from one-seventieth to one-fourteenth of a grain have been employed successfully by Dr. BATSCH of Grossenhain in cases of intestinal obstruction where the symptoms were subacute or where there was necessity to temporise. In some cases a single injection sufficed to produce an evacuation, followed by recovery. In others, the injection resulted only in the escape of flatus and a small quantity of fæces, definite relief only following a second injection on the next day.

Aspirin, the salicylate of acetyl, has been used successfully as a substitute for salicylate of soda. The new compound decomposes in the presence of an alkali so that under ordinary circumstances the stomach is unaffected and it is claimed in consequence that the disagreeable by-effects such as nausea and tinnitus are avoided in similar doses, while the anodyne and anti-rheumatic effects are the same.

Quinic acid, found by WEISS to possess the power of restraining the formation of uric acid in the system, has been combined with piperazine which exerts a solvent action. Experiments with quinate of piperazine showed that the diminution in uric acid when from five to eight grammes were administered daily, amounted to from 40 to 50 per cent., its place being taken by hippuric acid. The new drug exerts a great influence over gout and the uric acid diathesis. It is readily soluble and is given in five-gramme doses in two parts daily (30 to 40 grains twice a day).

Among the new derivatives of opium alkaloids heroin and dionin have both proved of value as sedatives, especially in cough. Of the former one-twenty-fifth-grain tabloids are effective, while the latter is given in doses of one-quarter of a grain. The products of coal-tar have furnished kryofin, possessing similar properties to phenacetine. The dose required is from one-half to three grammes (7–45 gr.) daily in divided doses, and its influence is chiefly in reducing temperature and as an anodyne. Pyramidon, dimethyl-amido-antipyrin, like antipyrin, reduces temperature but is thrice as active. The dose is from two to ten grains. It also relieves headache. The use of suprarenal gland has been extended with benefit to rickets and also to exophthalmic goitre. Vicarious action has been proved as regards metabolism between the ovary and thymus, which is further confirmed by the improvement obtained in chlorosis, exophthalmic goitre, and congenital debility by the administration of thymus gland in daily doses of from 15 to 30 grains.

SURGERY.

Surgery of the Alimentary Canal.

The surgery of the alimentary canal has probably attracted more attention during the present year than any other branch of the subject, and this is to be attributed chiefly to the fact that this portion of the body calls more frequently for surgical aid than does any other part or organ. In March Professor MAYO ROBSON delivered at the Royal College of Surgeons of England three lectures on the surgery of the stomach and a very good account was given of the present state of our knowledge on this subject. One of the most important questions raised by the progress of surgery in this organ is, Should any surgical treatment be applied to ulcers of the stomach when no perforation has occurred? At present the answer seems to be that an ulcer of the stomach does not need surgical interference until medical treatment has been thoroughly tried, but that if it should prove not amenable to medical treatment then surgical treatment is desirable. There are, however, two complications of ulcer of the stomach that require the intervention of the surgeon at an earlier stage. These are perforation and hæmorrhage. The operation for a perforated gastric ulcer has undergone no material change lately, but it is becoming distinctly rarer for the peritoneal cavity to be washed out by a large quantity of water, as was formerly the rule, and it is now more usual for the surgeon to content himself with wiping out so much of the effused material as can be reached. The results are certainly more satisfactory. The treatment of hæmorrhage from an ulcer of the stomach is as yet in a more unsettled state. Though laparotomy has been performed in many instances for acute hæmorrhage from an ulcer of the stomach, yet it is very doubtful if the results of this procedure are at the very least more favourable than those attainable by medical means. When, however, the hæmorrhage is chronic and persistent in spite of the regular employment of suitable medical treatment, then an operation is perfectly justifiable. What operation should be performed it is not so easy to say, but on the whole gastro-enterostomy seems to be the most likely to be of service. The cases of total extirpation of the stomach continue slowly to increase in number. Dr. VIEIRA DE CARVALHO has described in our columns one such case. It is difficult to believe that the necessity for such an operation can frequently arise, and it is not probable that the operation will ever become anything but very rare. The most satisfactory operation for obstructive dilatation of the stomach is not yet fully determined. Pyloroplasty, or the Heineke-Mickulicz operation, does not occupy quite so high a position in the opinion of surgeons as formerly, and its place has been taken in great part by one or other form of gastro-enterostomy. Mr. L. A. BIDWELL described 16 of these cases, for six of which gastro-enterostomy was performed, in three a pyloroplasty, and in three a pylorectomy. Only one patient died, and that death occurred two months after the operation.

Appendicitis still receives much attention and has been the subject of numerous papers during the year. Mr. C. B. KEETLEY has described a method which he is in the habit of employing for operating in appendicitis. He makes an incision through the anterior abdominal wall above the anterior superior iliac spine and above and parallel to the outer part of Poupart's ligament, dividing everything except the peritoneum, which is carefully raised from the iliac fascia so that the surgeon approaches the deep surfaces of the appendix. Mr. KEETLEY claims that this method may be employed at any stage of an attack. Dr. A. A. WARDEN advocates the method of removal of the appendix which was introduced by Dr. DOYEN. It consists in crushing the base of the appendix, then ligaturing it at the line where it has been crushed, removing the appendix with the thermo-cautery, and then inclosing the end of the stump by means of a double purse stitch.

---

[2] Archiv für Kinderheilkunde, Band xxvii., Nos. 3 and 4.

We have published notes of several cases in which a persistent Meckel's diverticulum has given rise to obstruction of the bowels. This form of obstruction is by no means rare and is commonly met with in patients under 40 years of age. The majority of the patients recover if laparotomy be performed sufficiently early.

Both observation and experiment have demonstrated that removal of a large portion of the intestine is incompatible with life, but it is difficult to lay down any very hard-and-fast line as to how much may be removed with safety. Professor CARL SCHLATTER of Zürich in 1898 removed about six feet of small intestine from a young man and the patient has survived the operation two years, and an elaborate series of observations have been made as to the digestive powers of the patient. It was found that if care were exercised in the choice of food digestion was carried on without trouble and nutrition was well maintained, but that if the diet were unsuitable then digestion was very imperfect and the general nutrition failed.

There have been several successful cases of laparotomy for perforation of the intestine in the course of typhoid fever, and it is now generally agreed that the surgical treatment of this complication offers by far the best chance of a successful issue. In 21 cases in which it was done during the years 1895–1900 three recovered completely, and one other patient recovered from the operation but subsequently died from intestinal hæmorrhage.

Surgery of the Liver.

Although ptosis of the liver was described by CANTANI so long ago as 1865, yet it has not been fully recognised until comparatively recently, and surgical treatment was not employed until 1891, when hepatopexy was first performed. The operation in one form or another is now a well-recognised procedure and the present aspect of the subject is well set forth in a clinical lecture by Mr. FREDERICK TREVES which appeared in the columns of THE LANCET.

The danger from an extensive rupture of the liver is exceedingly great, for its tissue is very vascular and the hæmorrhage is always severe. Slight lacerations which end in spontaneous recovery and cases in which an encysted effusion may form are not rare, but there have been very few cases in which a successful attempt has been made to treat surgically a laceration of the liver. Mr. THOMAS CARWARDINE has reported such a case and he has been able to find only three others in which the patient has recovered.

Fractures and Dislocations.

The best treatment of fractures of bones is still a *quæstio vexata*, especially with some surgeons. A large number of surgeons, perhaps the majority, are quite satisfied with what may be called the ordinary method of treatment of simple fractures. But there are others who claim that with the methods in ordinary use the affected limb is incapable of being used naturally in nearly every case for a long period, while in many others the disability is permanent. There is much to be said on both sides and the subject was discussed at the annual meeting of the British Medical Association. It appears to be certain that the fixation treatment of fractures is sometimes carried to excess and that an earlier recourse to movement and to massage would be followed by a diminution in the stiffness which is so liable to follow the prolonged incarceration of a limb between rigid splints. Mr. W. H. BENNETT contributed a valuable paper on the subject. There are, however, others who claim that in a large proportion of the cases of fracture of the long bones it is quite impossible by manipulation to replace the fragments in their original positions, and that this should be done by laying open the fracture by an incision, and after replacing the fragments wiring or screwing the broken bone so as to keep the fragments in position. The chief advocate of this practice is Mr. ARBUTHNOT LANE. It is true that it is frequently impossible by manipulation to replace exactly the displaced fragments of the bone, but it is also true that in most cases the amount of the deformity is very slight, so slight as generally not to interfere in any way with the efficient use of the limb. There are, however, certain cases in which it is quite impossible to put the fragments into a satisfactory position, and in such cases the surgeon is fully justified in wiring. At the present time if the surgeon has any doubt as to the position of the fragments after putting up the limb he should obtain skiagrams of the limb from two points of view and this may be done without disturbing the splints. Dislocation of the shoulder-joint from muscular action is a somewhat rare accident. A case recorded by Dr. J. GRIMMOND SMITH occurred in a man, 46 years of age, who was a congenital imbecile. The fracture of the os calcis by the sudden contraction of the calf muscles is also very unusual. Dr. R. THOMSON has described a case of this accident, and the fracture resulted from a sudden and forcible flexion of the left ankle, and a portion of the os calcis of the size of a walnut was pulled away by the tendo Achillis, and a space of about five inches separated the two fragments. Under an anæsthetic it was easy to bring the two fragments into apposition and they were wired, and the patient recovered.

Dr. J. D. RICE had a case of fracture of the femur in a new-born child which he treated by flexing the injured limb on the abdomen so that the foot was over the shoulder of the same side. The bone united well without shortening.

Two rare cases of separation of epiphysis were recorded; in one a skiagram showed that the epiphysis of a metacarpal bone had separated, and in the other the epiphyseal head of the femur had separated in a girl, 15 years old.

The Lengthening of Tendons.

The operation for lengthening a tendon is still by no means a common one, though it is now many years since it was first performed. Dr. R. A. HIBBS has described an ingenious method of obtaining more increase of length than was possible by the usual method, and he has employed it successfully in five cases of talipes equino-varus the result of infantile paralysis. A case of great interest was described by Mr. HERBERT W. PAGE who had under his care a little boy suffering from Volkmann's ischæmic paralysis, the result of the application of splints for a fracture of the lower end of the humerus, or separation of the lower epiphysis on the humerus. The range of movement was so slight that Mr. PAGE decided to lengthen all the flexor tendons. This was done and a very marked improvement in the power of movement resulted.

Tetanus.

Tetanus as a complication of a surgical operation is now very rare, at least in this country, and therefore a case recorded in which it followed nephropexy for floating kidney is of much interest. As great care seems to have been taken in guarding against sepsis it is just possible that it was not due to the operation but was the result of an accidental inoculation.

Bullet Wounds.

It was only natural that the subject of bullet wounds should have received a large share of attention during the past year since a war has been in progress. The character of the wounds inflicted by the Mauser bullet excited no small measure of surprise amongst those surgeons who, like Sir WILLIAM MAC CORMAC, remembered the effects of the needle gun and the Chassepot. The Mauser bullet wounds were characterised by a rapid recovery in those cases in which no bone or important vessel had been struck. Often when a bone has been hit the bullet has drilled a clean hole through it without splintering. In other cases a bullet has traversed the abdomen and has apparently perforated the stomach or intestine, and yet no symptoms have appeared. It is true that in some cases the bone that has been struck by the bullet has been much comminuted, but even then complete consolidation may follow in spite of the compound nature of the fracture.

GYNÆCOLOGY AND OBSTETRICS.

During the past year there has been no diminution in the output of gynæcological and obstetrical literature. A great deal of good work has been done, and many accepted views have undergone criticism, rejection, or confirmation.

In a paper upon the Anatomy of the Uterus in Infancy and Childhood V. MANDACH reports that amongst 80 cases the Wolffian duct was present in 32 and remains of the duct in 14. The cervical mucous membrane is well developed at an early age, but in the body of the uterus very few glands are present before puberty. The limit between the squamous and the cylindrical epithelium is sometimes very definite, at other times the one gradually passes into the other. He found polypi at the internal os in no less than 35 cases.

Amongst gynæcologists fibroid tumours have as usual excited a great deal of discussion. Their natural history has been considered by Dr. F. H. CHAMPNEYS and Mr. ALBAN DORAN. The former, in a paper[1] read before the North London Medico-Chirurgical Society which was based upon the statistics of St. Bartholomew's Hospital, contends that the frequency of fibroid tumours is 0 01 per cent. in a population of 959,217 and that the mortality apart from operations is 0·000138 per cent. The views of Dr. CHAMPNEYS met with a good deal of criticism, and although, no doubt, the mortality from fibroid tumours is very low, yet his method of determining the percentage mortality by dividing the number of fatal cases seen in the post-mortem room into the number of female out-patients during a given period appears liable to fallacy. Mr. DORAN opened an interesting discussion upon fibroids at the meeting of the British Medical Association at Ipswich and showed how little we really know of the laws governing the development and growth of these tumours. Papers have appeared in THE LANCET by Dr. WILLIAM DUNCAN and Dr. W. J. GOW which illustrate how low the mortality from operations for fibroids may be at the present day. The former has operated upon 68 consecutive cases with four deaths and the latter upon 47 cases with only one death. With regard to the technique of such operations Professor HOWARD KELLY has published an important paper illustrating his method of dealing with very difficult cases, such as large adherent tumours or intra-ligamentary fibroids. He describes three ways of treating such cases: (1) median sagittal bisection of the tumour; (2) coronal bisection of the uterus; and (3) bisection of the tumour alone.

The treatment of cancer of the uterus was the subject of discussion in the Gynæcological Section at the International Medical Congress at Paris. Dr. RICHELOT in his report advocated vaginal hysterectomy very strongly. His mortality was only 6 per cent, and he could point to 18 patients who had benefited by the operation. He regarded the scope of abdominal hysterectomy as being very limited, and did not believe in the practice of "removing everything." The comparison with the removal of the breast and clearing out the axilla was entirely misleading. Professor DMITRI DE OTT also reported on the surgical side of the question. He thought surgical treatment the sole means of combating cancer of the uterus. It was possible to effect a complete cure by operation. He had observed a radical cure—viz., freedom from recurrence for six years—in 10 per cent. of his cases. Dr. CULLEN in his report described WERDER'S method of performing abdominal hysterectomy. In this operation the uterus is freed on all sides, the vagina is dissected free from the bladder and rectum, and the uterus is removed from the vagina after the pelvic and abdominal cavities have been closed. There is therefore no danger of the operator coming in contact with the carcinomatous cervix. Dr. A. H. N. LEWERS read a paper before the Royal Medical and Chirurgical Society upon the After-results in 40 Consecutive Vaginal Hysterectomies for Cancer of the Uterus. In 12 cases there had been no recurrence, in 18 there had been recurrence, while four patients had died. 11 patients had remained well for from two to seven years. The condition of patients who have an inoperable cancer of the uterus is so distressing that any method which holds out a prospect of improving the means of dealing with such cases is to be welcomed. GRUSDEW thinks that the use of carbide of calcium, first introduced by GUINARD in 1896, is a method of practical value. It depends for its action on the decomposition of the calcium carbide into acetylene gas and unslaked lime. It can be used in the out-patient department. The ulcerated surface is cleansed with wool and one or two pieces of calcium carbide are applied and kept *in situ* with a tampon. They are removed in a day or two with the dead tissue and are re-applied if necessary.

Last year CATHERINE VON TUSSENBROEK described a case of Internal Ovarian Pregnancy occurring in one of the Graafian follicles. From her observations she concluded that the occurrence of ovarian pregnancy could no longer be contested and that the case showed a normal development of syncytium which she regarded as a new proof that the syncytium is developed from the fœtal ectoblast. The validity of this case has been criticised a good deal during the past year and, as Mr. BLAND SUTTON has pointed out, there is no evidence of the presence of chorionic villi in the description or drawings and he is therefore disinclined to accept it as a proved instance of ovarian pregnancy.

A very interesting case of prolonged gestation was reported in THE LANCET of Jan. 13th (p. 94) by Dr. JOHN PHILLIPS, in which delivery occurred 311 days after a single intercourse. This same question came up in a case before the courts and was noticed by us at the time. In this instance the jury evidently took the view that the pregnancy had not lasted 311 days as it was sought to prove, but no doubt they were influenced by other extraneous evidence upon this point. Dr. PHILLIPS'S case is of course also open to question, since it is always difficult to prove coitus on one single occasion.

Evidence is accumulating as to the safety and dangers of medullary narcosis. MARX reports six cases of labour treated in this way. Ten minims of cocaine containing one-sixth of a grain were injected into the spinal canal between the third and fourth lumbar vertebræ. In four of the cases the child was born without the patient knowing it. In one of the cases the cervix was dilated painlessly, while another case was a failure owing to the inertness of e cocaine solution. All the patients complained of tingng in the legs and headache. The record is a very nteresting one, but this method of treatment is hardly likely o come into general adoption.

---

[1] THE LANCET, Jan 20th, 1900, p. 147.

An important paper was contributed by Professor WHITRIDGE WILLIAMS to the June number of the *American Journal of Obstetrics* upon Placental Infarcts. He agrees with EDEN and other observers that this condition is usually the result of endarteritis of the vessels of the chorionic villi. Moderate degrees of infarct formation have no pathological significance, but when the infarcts are numerous and large they are often associated with death and mal-development of the child. They occur frequently in association with albuminuria, but the relationship of the conditions is unknown.

In his address in Obstetrics at Ipswich Dr. W. J. SMYLY[2] gave a review of the question of maternal mortality in childbirth during the present century. From the statistics of the Rotunda Hospital he found that during the period (1870–1876) 8092 women were delivered in the hospital, of whom 169 died, or one in 45·5; during a second period (from 1890–1896) 9085 were delivered, with 50 deaths, or one in 181·7, a saving of about 200 maternal lives in 10,000 deliveries. It was certain that, in hospital practice at any rate, a marked improvement had taken place during the last quarter of the century amongst all the three classes of fatal cases met with in childbirth—viz., puerperal fever, accidents of labour, and other causes. In view of the fact that where there was no "handling" there was no septic infection he advocated very strongly indeed the avoidance as far as possible of vaginal examination and the practice of abdominal palpation. The important question of the notification of puerperal fever was discussed in the Obstetrical and Gynæcological Section at the same meeting. In spite of the difficulties that lay in the way of carrying out complete notification most of the speakers were in favour of its being done. Dr. BERRY HART, who opened the discussion, was strongly in favour of notification. He thought, however, that more than this was necessary, and that municipalities must provide skilled nursing where necessary, removal to a properly equipped hospital when desired, supervision of nurses and midwives when solely associated with the management of a case, and supervision of their proper disinfection before they took up fresh work. It was of great importance that the matter should not begin and end in mere registration. Dr. R. BOXALL drew attention to the fact that while during the 10 years 1881–1891 the death-rate from puerperal fever in London was 21·5 and in the provinces 25·6 per 10,000 confinements, during the last seven years, 1892–1898, it was 19·2 and 24·1 respectively—figures which showed that there had been practically very little change in the rate of mortality from this disease. After considerable discussion, in which it was stated by several speakers that compulsory notification would be very prejudicial to medical men, the following motion was adopted:—

That in the opinion of this meeting it was desirable that notification of puerperal fever (septicæmia) should be adopted generally.

The second obstetrical subject for consideration before the meeting was the treatment of post-partum hæmorrhages. The discussion was opened by Professor BYERS, who declared himself in favour of gauze-plugging of the uterus rather than bimanual compression of the uterus in severe cases where the hot douche and other means had failed to excite uterine contractions.

Two important papers were read before the Obstetrical Society of London upon Incarceration of the Retroverted Gravid Uterus by Dr. J. SINCLAIR and Dr. MUNRO KERR. The latter reported amongst others the case of incarceration of the retroverted gravid uterus with hæmorrhage into the after catheterisation operated upon by Mr. MURDOCH CAMERON. He performed abdominal section, opened and emptied the bladder, and replaced the uterus. Dr. SINCLAIR in his paper protested against the performance of unnecessary operations in these cases. He recommended the introduction of a hard ring pessary, a method which usually resulted in speedy replacement of the uterus. In cases where sloughing of the bladder wall was imminent he would open the bladder by vaginal cystotomy, and he thought the same plan of treatment would answer quite well if hæmorrhage occurred into the bladder. In the discussion upon these papers most of the speakers said that reposition with or without an anæsthetic was all that was required in the great majority of instances.

An interesting paper was read before the same Society by Dr. THOMAS WILSON on Organic Affections of the Heart occurring in connexion with Fibro-myomata of the Uterus. The important question of the best mode of treating cases of rupture of the uterus was considered by Dr. HERBERT SPENCER. He concluded that abdominal section was rarely required and almost solely in cases where the fœtus had passed completely or in part into the peritoneal cavity. It was best done under local anæsthesia. Abdominal hysterectomy was hardly ever necessary, vaginal hysterectomy where the broad ligaments were very much damaged being a preferable operation. All incomplete tears implicating the broad ligament and most complete tears should be treated by packing the rupture per vaginam with iodoform gauze after removing clots and fluid blood. Dr. AMAND ROUTH made a very valuable contribution upon Porro-Cæsarean Hysterectomy. He considered it to be a poin worthy of discussion whether supra-vaginal amputation of th uterus (Porro's operation), with retro-peritoneal treatment the stump, was not safer for the patient in skilled hands tha a Sänger Cæsarean section with sterilisation, in all cases permanent obstruction to labour requiring abdominal secti except, perhaps, those due to cancer of the supra-vagi portion of the cervix.

In the section of obstetrics at the International Med Congress at Paris a discussion was held on the Etio and Nature of Puerperal Fever. Reports were presente MM. DOLÉRIS, MENGE, and KRÖNIG and PESTALOZZA. bacteriological aspect of the question was the one was mainly considered and in view of the special ledge of the authors their conclusions are of great The interesting question of the possibility of the occu of autogenetic injection was fully considered. M. D said that from the clinical point of view they were b admit the reviviscence *in situ* of pathogenic germs p ing in the cervix uteri and Fallopian tubes, and the po of such an infection becoming generalised after con without any fresh importation of pathogenic micr without. By autogenetic puerperal injection Dr. M Dr. KRÖNIG understood an infection produced by bacteria that have lived in the condition of sa before labour on the integuments of the externa or in the genital canal of the woman, and which, confinement or immediately after it, had in organism through the puerperal wound and set Taking clinical facts as a guide, the authors rare and favourable the autogenetic puerperal i duced by such saprophytic organisms. An infection produced by bacteria that had liv phytes in the cervical canal or in the cavity or in the tubes, could be absolutely reject organs never contained bacteria in the saprophytes. The primary infective foc commonly situated in the endometrium, mor cervix, and most rarely in the vagina or PESTALOZZA reported the results of his st channels by which the different pathogenic agents could penetrate into the tissues of a genital canal of a lying-in woman. The results of his researches had led him to the following conclusions. The aseptic course of events following delivery depended upon the rigorous disinfection of the external genitalia and of the hands and instruments of the obstetrician. Disinfection of the vagina and the use of douches before and after labour were useless and dangerous. If infectious symptoms arose it was of the greatest importance to determine the point of entry of the infection. He had only found the staphylococcus in the case of multiple abscesses in the wall of the uterus, and the bacillus coli communis in the case of fever arising from decomposition of the liquor amnii. The other obstetrical subject discussed was asphyxia neonatorum. Reports were presented by Dr. RIBEMONT-DESSAIGNES, Dr. CHAMPNEYS, and Professor SCHULTZE.

---

[2] THE LANCET, August 11th, p. 385.

The disinfection of the hands in view of the large number of cases of puerperal infection in which the contagion is caused by them is a matter of much importance. The best means of accomplishing this has been considered by a large number of observers during the past 12 months. It seems certain that absolute sterilisation of the hands is not possible. VARNIER says: "Brushing of the hands in hot soap-and-water for five minutes does not secure asepsis, consecutive immersions in alcohol and in a 1 in 1000 solution of perchloride of mercury or a 1 in 2000 solution of biniodide of mercury does not sterilise the hands, but practice has shown that although a few microbes can still be found after such treatment, yet the sterilisation is sufficient from the point of view of prophylaxis. The germs may not be destroyed but their activity is impaired." The use of thin rubber gloves which can be sterilised is a precaution of great value to the surgeon or gynæcologist who is compelled to handle infected material.

Publications.

Amongst the more important books that have been published are Varnier's "Obstétrique Journalière," the completion of the German Encyclopædia of Midwifery and Gynecology, edited by SÄNGER and VON HERFF, and a very interesting book on Cancer of the Uterus by Dr. CULLEN of Baltimore.

OPHTHALMOLOGY.

Lacrymal Obstruction.

Amongst the more interesting events that have taken place during the past year in Ophthalmology are the discussion on the treatment of lacrymal obstruction at the Ipswich meeting of the British Medical Association, which was opened by Mr. GEORGE BERRY, from whose conclusion that as a rule there is a tendency to do too much few of those who have seen many cases will be inclined to dissent. In the course of the discussion which followed the reading of the paper it appeared that there was not any very general consensus of opinion in regard to the treatment to be adopted even in the more simple forms of disease, and much less consequently in the more severe forms—some using small and others large probes; some slitting up the canaliculus and inserting straight silver or gold styles; others moulding flexible lead ones to the form of the duct and copying the form in gold. One speaker used a rose-headed drill or burr worked by the ordinary dental engine; another was content with syringing at first and slitting up the canaliculus if this plan were ineffective or even laying open the sac and either removing it or applying the actual cautery. It is curious that no one suggested that the teeth were sometimes at fault and that the extraction of the second bicuspid or first molar tooth is sometimes sufficient to effect a permanent cure. Mr. DONALD GUNN noted the frequency of lacrymal obstructions in infants and believes it to be associated with congenital obstruction at the lower end of the nasal duct.

At the same meeting Dr. W. A. BRAILEY in his introductory address dwelt on the various forms of ocular disturbances that may occasion headache and indicated the means of relief. He considered that muscular efforts either of the intrinsic or extrinsic muscles are by far the most common, especially those concerned in the effort to correct hypermetropia and astigmatism; and Mr. RICHARDSON CROSS of Clifton took for the text of his discourse the treatment of chronic glaucoma. He advocated the early performance of sclerotomy and adduced cases in which the field of vision had improved when the tension was relieved. Other speakers preferred the postponement of the operation to a late date, combating the symptoms with myotics.

An interesting case throwing some light on the trophic influence of the fifth pair of nerves on the cornea has been recorded by Dr. VEASEY of Philadelphia in which, after removal of the lacrymal gland for obstruction of the lacrymal duct, anæsthesia and subsequently inflammation of the cornea occurred notwithstanding that the eye was carefully protected. It would seem, therefore, that this case supports the views of those who maintain that the cause of such an affection is not of a mechanical nature and due to exposure of an insensitive cornea, but that it is the result of some disturbance of the trophic nerves. The case under judicious treatment made a complete recovery.

The Value of Enucleation.

The relative value of enucleation as compared with the various proceedings by which that operation can be replaced was well discussed at the International Medical Congress which met at Paris and also by Dr. DEMARIA of Buenos Ayres. As Professor PFLUGER of Berne remarked, enucleation has the advantage of being a simple operation capable of rapid execution, but it has the disadvantage of leaving a small stump which allows of but little movement in an artificial eye adapted to it. Various methods have been adopted to remedy this evil. Dr. MULES eviscerates the contents of the globe and inserts an aseptic glass or metallic ball, uniting the edges of the sclerotic and rendering the wound subcutaneous by drawing the conjunctiva over it; Mr. W. A. FROST and Mr. W. LANG propose to inclose the glass bulb in the capsule of Tenon; whilst Dr. SCHMIDT recommends attaching the recti muscles to the conjunctiva. Lethal meningitis has been observed in cases of enucleation of the eye affected with acute inflammation and suppuration, but it has also been observed in similar cases when no operation was performed. None of these proceedings is a complete safeguard against the occurrence of sympathetic ophthalmia, nor does neurectomy constitute a complete and permanent protection against it. Dr. DE SCHWEINITZ considers that enucleation is indicated in cases of recent and severe injury, whilst MULES'S operation should be performed in cases of staphyloma corneæ, of absolute glaucoma, and of non-traumatic iridocyclitis. Dr. H. R. SWANZY of Dublin practises MULES'S operation in all cases of enucleation, excepting those of malignant tumour or cases where sympathetic tumour is to be dreaded. M. DE LA PERSONNE prefers the actual cautery, as recommended by M. PANAS, in which a large thermo cautery at a white heat is applied to the interior of the globe. The débris of the membranes are removed and the wound is cleansed with cyanide or chloride of mercury. No bleeding occurs; no sutures are needed and pain is abolished.

Retraction Movements of the Eyeball.

Dr. JULIUS WOLFF of New York has described cases of retraction movements of the eyeball, a condition which has attracted but little attention. It appears to be associated with a congenital defect in the motility of the retracted eye and the retraction invariably takes place during attempted inward rotation, a forward movement of the globe occurring together with widening of the palpebral fissure on efforts to evert being made. He agrees with TUERK in attributing it to paralysis of the external rectus, which is converted into an unyielding strand of connective tissue.

Electric Light and Blindness.

That the employment of electricity is not quite free from danger to the eye is shown by a case under the care of Dr. UHTHOFF in which the rays proceeding from an arc light fell suddenly upon the left eye, the other being closed, with the result that a central scotoma was observed in the eye extending about 10° from the point of fixation. On ophthalmoscopic examination a number of yellowish-red points were found scattered about the macular region. Dr. DUNBAR ROY of Atalanta reports three cases where temporary blindness followed exposure to the flash of light due to the accidental crossing of two electric wires carrying a voltage of 500.

Colour-blindness.

Dr. W. THOMSON of Philadelphia has devised an instrument for diagnosing colour-blindness. It is composed of coloured glasses set in the periphery of a disc capable of revolving in front of a light. The glasses of this disc can be covered by a set of glasses set in a second disc of which one is white ground glass, one deep London smoke, one pink, one green, and one cobalt glass, and in addition one disc is perforated by holes of different size to moderate or to intensify the light. This instrument with Dr. THOMSON'S colour-stick constitutes the means of examination for the colour sense practised on the Pennsylvania Railway and on 150,000 miles of railroad in America. Dr. CHARLES WILLIAMS of Boston has also brought before the American Ophthalmological Society a lantern for testing colour perception. Dr. WARD HOLDEN and Mr. K. BOSSE of New York have made a series of experiments on children in regard to colour vision and find that under two years of age infants are chiefly attracted by reds. Then follow some years of comparative indifference to colour, but at the age of five or six blue is almost universally preferred.

The Mechanism of Accommodation.

The explanation of the act of accommodation advanced by VON HELMHOLTZ and given upon his authority in most textbooks was some years ago impugned by Dr. TSCHERNING, a Russian ophthalmologist of great ability. Briefly stated, the view of VON HELMHOLTZ is that in repose the lens is flattened by traction exerted by the zonule, whilst in accommodating for near objects the ciliary muscle contracts, and as its anterior margin is considered to be fixed it draws the choroid forwards, relaxes the zonule, and the lens becomes more convex anteriorly owing to its elasticity. Dr. TSCHERNING contended that the contraction of the ciliary muscle in accommodation rendered the zonule tense instead of relaxing it, and the pressure on traction exerted on the lens produced a kind of lenticonus or increased curvature anteriorly. Dr. W. N. SUTER of Washington, as the result of a series of experiments, pronounces in favour of VON HELMHOLTZ'S theory, maintaining that the increased prominence of the anterior surface of the lens in accommodation does, indeed, occur, but only in old animals—that is to say, precisely at a time when the accommodation faculty is failing or is lost and is then due to the bulging of the hard nucleus when the lens is flattened as a consequence of the relaxation of the zonule when the ciliary muscle contracts.

The Visual Area.

Dr. JOSEPH SHAW BOLTON has made an important contribution to Ophthalmology by his research on the exact histological localisation of the visual area of the human cerebral cortex, derived from a study of lesions causing blindness, and of the histological examination of the occipital cortex. The area chiefly occupies the body of the calcarine fissure, but extends to some adjoining parts. The portion of this area to which afferent visual impressions primarily pass is the region of the cortically situated line of Gennari, and it constitutes the cortical projection of the corresponding halves of both retinæ. The part above the calcarine fissure represents the upper corresponding quadrants and the part below the lower corresponding quadrants of both retinæ. It is sometimes of importance to see with the ophthalmoscope as far forwards as the tips of the ciliary processes. Dr. TRANTAS of Constantinople has suggested a means by which this may in most instances be accomplished—namely, by pressing with the finger on that region whilst the patient is under examination. As a rule, even when examined most obliquely the parts in front of a circle drawn at a distance of one-third of an inch from the sclero-junction are invisible. By pressure one-eighth, or even one-sixth, of an inch more may be brought into view. The anatomical seat of the lesions which are supposed with some show of reason to result from the toxic influence of alcohol and to lead to impairment of vision has been investigated by Dr. BASIL SIEGFRIST. It may be, seeing that complete recovery is often the result of appropriate treatment, that, as Mr. PRIESTLEY SMITH suggests, in many instances there are no lesions, but a certain pallor of the discs is of common occurrence, and if indulgence in alcohol is carried to excess atrophy of the optic nerve may ensue. By some this is attributed to interstitial inflammation of the connective tissue forming the trabeculæ, the proliferation and contraction of this material destroying the nervous tissue. Others hold that the nerve tissue is primarily attacked and its functions are impaired, the increase of the connective tissue being secondary. Dr. SIEGFRIST supports the former view.

The Treatment of Entropion.

The treatment of entropion was the subject of two papers and a discussion in the American Ophthalmological Society. The extreme irritation and discomfort of this condition as well as the danger of rendering the cornea opaque and causing loss of vision and the difficulty of effecting a cure have led to the adoption of many operative procedures, some of them of great antiquity. Where many operations have been proposed for a particular disease it may be taken for granted that no single one is always appropriate and successful. Some slight cases may be cured by the simple expedient of applying elastic collodion to the outside of the lid, others by the removal of a narrow horizontal strip of skin, others by horizontal incision of the conjunctiva and the insertion of a strip of skin taken from some other part of the body, as of the skin from behind the ear, others have applied electrolysis to the skin, and others have made an eschar with caustic potash. Dr. EWING of St. Louis makes a conjunctival flap, then a horizontal incision through the tarsus but not through the muscle, and everts the free edge over a small roll of lint by two or three sutures. The posterior flap of the divided conjunctiva is finally stitched into the angle of the wound. Dr. WEEKS of New York makes a cut along the whole length of the lid between the cilia and the Meibomian follicles and another one three millimetres below through the skin, he then removes a wedge-shaped strip of the tarsus and inserts a piece of mucous membrane into the wound.

Treatment of Magnetic Foreign Bodies.

Dr. COPPEZ of Brussels and ISODORE GUNZBURG have written an interesting article on the diagnosis and treatment of iron fragments that have penetrated the globe of the eye. Their observations, which are numerous, show that the chances of recovery with useful vision, though always doubtful, are far greater when the position of the fragment is in the anterior than in the posterior region of the globe. The means of diagnosis they employed was the magnetorium of **GÉRARD**, which they found to be simple, effective, and capable of easy manipulation. Dr. **LIPPINCOTT** of Pittsburg, Pa., employs for the purpose of diagnosing the presence of particles of iron in the eye a magnet weighing nine pounds and capable of lifting a weight of 50 pounds. Its application is facilitated by supporting it with a cord passing over a pulley and terminating in an equipoise.

Literature.

Dr. W. **NICOLAEW** and Professor J. **DOGIEL** describe in Pflüger's *Archiv* the mode in which they have obtained photographs of the inverted image of the fundus of the eye and give two photographs. The *Optician* issued weekly and intended primarily for the trade is a very well-conducted journal and contains much useful information on optical subjects. It has published during the past year **PEREIRA** on Refraction and Dr. **BREWSTER'S** Optics considerably enlarged and brought up to date. The fourth volume of Dr. W. F. **NORRIS** and Dr. C. A **OLIVER'S** valuable System of Diseases of the Eye by various authors has been published, containing an account of the motor apparatus of the eye, of the cornea and lens, and of the refraction of the eye. There is also a chapter on Medical Ophthalmology. Dr. **CHARLES MAY** of Columbia University, New York, has published a good manual of the Diseases of the Eye. The Refraction of the Eye, including a complete treatise on Ophthalmometry, has been written by Dr. A. **EDWARD DAVIS** and constitutes a very sound guide to the student and practitioner. Professor O. **HAAB** has published a third and enlarged edition of his useful Ophthalmoscopy which represents in chromo-lithography many of the diseases of the fundus.

Miscellaneous.

The careful observations of Dr. A. **PICHLER** during the year have demonstrated what previously was only believed to occur, that a partial decussation of the optic-nerve fibres takes place in the chiasma. The non-decussating portion occupies chiefly the lateral and dorso-lateral portions of the chiasma. In the optic tract they are situated in the dorsal two-thirds. The decussating fibres are situated mesially, and some of the fibres form short loops passing from one optic nerve to the other.

Cases continued during the year to be reported of high, or of rapidly increasing, myopia in which the lens has been removed with satisfactory results, Dr. **KOLLOCK** of Charleston, S C., for example, giving a case where after removal of the lens the vision with a low convex glass and astigmatic correction was such that the smallest print was easily read by the patient.

As iodoform is often freely dusted over the wound left after enucleation it is perhaps expedient to notice that various cases have been recorded in recent ophthalmological journals of impairment of vision due to the poisonous effects of iodoform. The symptoms observed have been attributed to the development of a toxin by micro-organisms in the eschar produced by the drug.

FORENSIC MEDICINE.

During the present year a large number of actions have been tried in the civil courts in which medical men have appeared as plaintiff or defendant and very generally with the result that the morale of the profession has been maintained and even enhanced.

Mr. J. L. A. **HOPE** sued the Chertsey Board of Guardians in the County Court for £7 7*s.*, his fees for examining seven persons for the purpose of certifying under the fifth subsection of the 24th section of the Lunacy Act of 1890. The Guardians, it will be remembered, proposed to pay only half a guinea for each case as, in their opinion, reasonable remuneration for the service rendered. The Act does not fix a definite sum, but it was shown that one guinea was the amount usually awarded and judgment was very properly, we think, given for the plaintiff.

The resident medical officer of the Leeds Public Dispensary and his locum-tenent were summoned at the instance of the Registrar-General for having contravened the provisions of the Births and Deaths Registration Act of 1874. The former gentleman attended a child at the dispensary. He was afterwards absent from the institution for a time, leaving some open death certificates signed by him. 15 days after the child was taken to the dispensary the locum-tenent, who had no personal knowledge of the case, filled in the particulars as to the cause of death on one of the forms referred to. It was not contended by the prosecution that there had been any attempt wilfully to issue a false certificate; nevertheless there had been great irregularity. The magistrate imposed a nominal fine in each case, "the amount of the penalties being paid as the costs of the prosecution." We took occasion to endorse the action of the Registrar-General, maintaining, as we have always done, that certification of death should be in strict accordance with the terms of the Act.

In the Queen's Bench before the Lord Chief Justice Messrs. **ANDERSON** and **FENNER** sued a Mr. **MOELLER** for the payment of fees for professional services. It was pleaded in defence that the charges were exorbitant, and that there had been want of proper care and attention. Evidence was called to refute the latter plea, and successfully, for after a most able and lucid summing-up by the Lord Chief Justice, the jury found for the plaintiffs, though for a smaller sum than was claimed.

A very interesting case was concluded at an adjourned inquest at Hastings on Nov. 17th. An elderly lady received an injury to the hip. After leaving the local hospital she came under the care of Mr. H. R. **MANSELL**. This gentleman wishing to clear up a doubtful diagnosis employed a chemist to take a radiograph. One result of the procedure was that a skin eruption with subsequent extensive ulceration developed at the site of application of the instrument. The distance of the focus-tube from the skin was not mentioned. Evidence was given that the apparatus was somewhat antiquated. The exposure seemed to have been unusually prolonged. The jury found that no blame attached to the medical man or to Mr. **BLOOMFIELD** who took the skiagram. In commenting on the case we expressed the opinion that considering the possible mishaps the Roentgen rays should be applied by the medical man himself or by some other skilled qualified operator.

SHAW *v.* the Railways Passengers Assurance Company, which was adjudicated upon by a court of arbitration, raised two very important pathological and incidentally clinical questions. The deceased man was thrown from a cart and received severe internal injuries. After temporary improvement he got worse, and died 10 weeks after the accident. At the necropsy a soft mass was found filling the pelvis, which the medical men who attended the deceased concluded was a degenerated blood-clot. A microscopical examination was made by the Clinical Research Society and the result reported as showing a soft sarcoma. From their finding we gathered that the arbitrators were of opinion that the examination of a single microscopical section of the mass was not sufficient to distinguish between a round-celled sarcoma and granulation tissue, or that, granted the existence of the former it was not proved beyond reasonable doubt that the injury might not have been the exciting cause of the growth. These assumptions received our endorsement.

As in our last annual record, so now, we express our unfeigned satisfaction at the marked diminution in the practice of criminal abortion by medical men. It would seem that the merited condign punishment meted out to unworthy members of the profession has had a deterrent effect upon would-be contraveners of the law—if such there are. There seems, however, too much ground to fear that the crime in question has by no means fallen into desuetude as regards abortion-mongers. At the Central Criminal Court on Nov. 20th ERNESTINE KATZ, a German, was sentenced to 10 years' penal servitude. From documents found on her it appeared that she had been charged in 1897 at Berlin with the same offence and had absconded from her bail.

The crusade against the publication and sale of obscene literature has met with considerable success. We trust that the authorities will continue their attempts to suppress this fertile source of moral pollution. "Professor WELLS," a sexual quack, got no more than his deserts when he was sentenced to 12 months' imprisonment for using in a public place obscene and filthy language, and for having published an obscene book.

Overlying still contributes largely to the record of infant mortality. Much of the sacrifice of life in this way might be easily prevented, as we have pointed out, by putting young children in separate beds instead of allowing them to sleep with their parents. It seems reasonable to infer that criminality as well as carelessness accounts for many of the deaths from overlying which are attributed to accident, although the difficulties in the way of determining the facts are in most instances insurmountable. A woman was committed for trial at the North London Police-court for having negligently attended her child whilst in bed with it. She had previously lost two of her children from "overlying."

A remarkable instance of ice-cream poisoning occurred in Rochdale. A large number of people were attacked with gastro-intestinal symptoms, and one person died. The constituents of the "cream" would seem to have become infected from having been placed in contiguity with excreta from the human alimentary canal. The case points to the necessity not only of providing cream free from organisms and the products of their fermentative action, but of preserving the same from after-contamination.

Very few cases of homicidal poisoning have to be chronicled. Accidental and suicidal poisonings, on the other hand, have claimed their wonted share of victims.

Our knowledge of the action of poisons has been amplified in some cases and emphasised in others. The recently discovered existence of arsenical beer poisoning on a wide scale has revealed the original source of the evil. At the same time it has raised the whole question of artificially prepared foods and drinks. Moreover, we have been led to compare the effects of certain consequences of arsenical poisoning with those of chronic alcoholism and the disease beri-beri. Both arsenic and alcohol cause peripheral neuritis. The pigmentation from arsenic unfortunately occurs too late to raise a timely warning.

The provisions under the Sale of Food and Drugs Act are not sufficient to safeguard the community. Further legislation to compel specification is needed. In THE LANCET of Jan. 20th, p. 177, we wrote: "The preparation of maize glucose is, however, conducted with great care and there is no reason for doubting the wholesomeness of the product." Arsenic has not yet been found in artificial golden syrup, we believe.

Dr. LOUIS P. HAMBURGER has published in the *Johns Hopkins Hospital Bulletin* an instructive case of chronic arsenical poisoning, in which the prominent features were pigmentation, keratosis, and ascites. It seems to be not improbable that arsenic may have a direct effect upon the serous membranes as well as upon the nervous, mucous, and cutaneous membranes. M. ANDRÉ PETIT and M. HUDELO, in papers read before the Société Médicale des Hôpitaux, have discoursed on the relation of plumbism to parotitis. They found lead in the saliva. It seems likely that parotitis may be caused (1) by the irritant action of the lead during salivary excretion and (2) by spreading of the inflammation from the buccal mucous membrane. Industrial lead poisoning has received attention and the recommendation of the chief inspector of factories that each successive attack of lead poisoning in the same individual should be notified is likely to prove a signal service.

In the *American Journal of the Medical Sciences* Dr. F. B. HARRINGTON has related a series of 132 cases of gangrene from the continued application of dilute solutions of carbolic acid. In some instances a 2 per cent. or 3 per cent. solution applied for 24 hours or less sufficed. In MERCK'S Archives attention was drawn to the antidotal action of alcohol as regards carbolic acid. It can be given in the form of brandy or whisky. It is recommended that a weak solution of sulphate of soda be used to wash out the stomach and that the same salt should be administered subsequently. A new process has been devised for estimating quantitatively mercury in the urine. The urine to which stannous chloride has been added is poured on an asbestos filter containing particles of gold derived from auric chloride. The difference between the weight of the dried filter before and after the expulsion of the mercury by volatilisation gives the amount of mercury. We consider the old plan of electrolysis to be preferable.

Dr. COLEMAN of New York has described a case of poisoning by trional. The patient, a woman aged 35 years, suffering from mild alcoholic delirium, took 540 grains of the drug. The chief symptoms were thickness of speech and ataxy. Dr. TAYLOR and Dr. SAILER, in their contribution from the WILLIAM PEPPER Clinical Laboratory, University of Pennsylvania, gave the history of a case of fatal poisoning by sulphonal. The victim was a woman, aged 52 years. There was difficulty of speech, sighing dyspnœa, hæmatoporphyrinuria, and stiffness and paralysis of both legs. Death resulted from cardiac failure. Post mortem the internal organs showed fatty degeneration. There was pigmentation of the spleen and lymphatic glands.

In the *Edinburgh Medical Journal* Dr. JAMES FOULIS has described two simultaneous cases of poisoning by cannabis indica. The patients, two students, took in successive doses 25, 40, and 90 minims of the tincture with a view of "experiencing the wonderful dreams" produced by the drug. The symptoms were marked mental and muscular stimulation. In JACOB'S Festschrift, 1900, Dr. B. SCHARLAN has illustrated the value of curare in the treatment of tetanus by three successful cases.

Coal-gas accounted for the death of a man at Birmingham. The gas escaped through the failure of the water seal—a most dangerous arrangement—in a chandelier fitted with a water-slide pendant. A man and his son were killed by the inhalation of gas which had escaped from "a shilling in the slot meter." The gas company's employé had omitted to test the meter, a circumstance upon which we animadverted.

DENTAL SURGERY.

The past year has given clear evidence that the medical profession is becoming fully alive to the important rôle which an aseptic mouth plays in the maintenance of good general health. In an excellent series of communications to THE LANCET in the early part of the year Dr. WILLIAM HUNTER showed that pernicious anæmia is probably a chronic infective disease with marked gastro-intestinal symptoms. The infection he considered in the majority of the cases to be directly traceable to the mouth. Mr. RICKMAN GODLEE, in a paper read before the Royal Medical and Chirurgical Society, drew attention to serious conditions which were apparently traceable to infection from a suppurative periodontitis. Not only has the question of septic infection from the teeth received attention from the medical profession but the subject of early decay of the teeth has been brought prominently forward by the first report of the committee appointed by the British Medical Association. The report, although it adds nothing new to our knowledge of caries, is nevertheless an able *résumé* of the question and forms a good basis for further researches.

Papers on Superior Protrusion (prominent upper teeth) have appeared from the pens of Mr. T. E. CONSTANT, Mr. E. LLOYD-WILLIAMS, and Mr. J. F. COLYER. Mr. CONSTANT dealt briefly with the question of etiology, Mr. LLOYD-WILLIAMS and Mr. J. F. COLYER with treatment. In the paper by the latter early interference — namely, before the eruption of the canines—was recommended, and it was shown by models of cases before and after treatment that by this means better results can be obtained than when treatment is delayed until the appearance of the second permanent molars. A paper on the Treatment of Misplaced Teeth by Alveolotomy has been contributed by Mr. W. H. DOLAMORE. This method consists in the immediate regulation of teeth by making incisions through the whole alveolus on either side of the misplaced tooth and bringing the tooth, with its encircling structures, either forwards or backwards as required. The method seems destined to prove useful for the correction of misplaced teeth in adults.

An excellent article has appeared on Antral Abscess by Mr. J. G. TURNER. The writer points out the unsatisfactory results which follow opening of the antrum through sockets of teeth and strongly recommends the operation through the canine fossa, as by this means all parts of the antrum can be reached and the mucous surface curetted. Attention is also drawn to the frequent prolongation of the antrum into the nasal process. This portion of the antrum is inaccessible and is often overlooked by the operator, thus continuing a focus of infection. Investigators have been busy investigating the micro-organisms connected with caries and useful communications have been published by M. CHOQUET and Mr. A. L. GOADBY. The mummification of pulps has again attracted attention and it seems quite possible that some of the methods which are being tried may prove of great utility for the treatment of the pulp in difficult cavities.

A case of multiple necrosis, supposed to be traceable to septic infection from a tooth, was recorded by Mr. BREWARD NEAL. The cause was an obscure one and would have been more interesting if in recording the case it had been stated what care had been taken to exclude other causes. A large number of records of cases in which a relationship is supposed to exist between dental and general conditions are too often rendered valueless by want of care in excluding the possible or probable causes.

Mr. M. HOPSON has reported an instance of hypertrophy of the gums existing in three members of a family—the father and two children—one interesting feature being that in the father a sarcoma springing from the upper part of the maxilla appeared.

In the practice of dental surgery progress has been made in the treatment of cavities by means of porcelain inlays. It is to be hoped that this work, which in its place is excellent, will not become a lever for quackery.

The x rays have been more employed as an aid to diagnosis during the past year, and the paper read by Mr. GOLDIE before the Odontological Society of Great Britain showed their great value. In probably no other branch of surgery are the rays more useful, and it is to be hoped that the dental hospitals, like the general hospitals, will institute proper departments. Dental surgeons and those in authority as teachers do not seem to have yet grasped the value of this means of diagnosis.

The annual meeting of the British Dental Association was held at Leeds under the presidency of Mr. G. BRUNTON. An important discussion took place on the Teaching of Mechanical Dentistry, and another feature of the meeting was the number of papers and demonstrations on the subject of crowns.

The past year has seen another International Dental Congress, Paris being the rendezvous. The gathering was a distinct success and many of the papers which were read were of more than usual merit.

The importance of providing dental surgeons to the services formed the subject of a communication by Mr. N. G. BENNETT, and there is reason to believe that the question is receiving official attention. If such officers are appointed it is most important that they should hold not only dental but also medical qualifications.

Publications.

There have been but few new books published; Mr. J. J. FITZGERALD'S little work on "Pyorrhœa Alveolaris" has reached a second edition. Dr. SIM WALLACE has published a book on "The Etiology of Caries," Dr C. N. JOHNSON one on "The Principle and Practice of Filling Teeth," and Mr. J. F. COLYER one entitled, "Notes on the Treatment of Irregularities in Position of the Teeth."

Obituary.

The obituary of the year includes Mr. JAMES WALLACE of Paisley, Mr. J. H. REDMAN of Brighton, Mr. C. MORLEY of Derby, and Mr. J. B. FLETCHER of London. The dental profession has also to regret the loss of Mr. STORER BENNETT and Mr. T. UNDERWOOD.

ANATOMY AND PHYSIOLOGY.

Although no very remarkable advance can be chronicled in regard to the progress of physiology during the past year, yet, like the ripples of the rising tide, a constant accession of facts may be observed which serve to eliminate former errors, to strengthen and establish the truths which may even yet be in need of support, and to open up new paths of research. It is pursued with singular perseverance and ability in Germany, and so numerous are the articles that have been published in that country that it has become impossible even for those who have devoted themselves to its study to read more than a small proportion of them. Pflüger's *Archiv für Physiologie*, which is only one amongst several journals devoted to physiology, forms four large volumes of 640 pages each and contains upwards of 100 articles, many of them running to a length of 30 or 40 pages, for the present year alone. In taking a general survey of this field of science it may be noted that a considerable number of the papers read before societies and contained in journals are devoted to the chemical side of physiology. Taking at random, for example, one or two of the parts of the journal we have just mentioned (Pflüger's *Archiv*) we find articles on the quantitative determination of glycogen, on the proportion of urea in human milk, the position of the purin or xanthin bodies in general metabolism, on the presence of proteolytic and amylolytic ferments in the colon, and on the absorption of fat without previous saponification. So, too, in Reichert's *Archiv* we find essays on ferments, on the absorption of food, on the preliminary stages of glycogen in the body, and on the colouring matters of the blood; and in the *Journal of Physiology* we have contributions to the physiological effects of peptone when injected into the circulation, the pressure filtration of proteids, the metabolism of phosphorus, and on the separation of a pure albumin from white of egg. If progress be made on these lines it is clear that our knowledge of the processes by which the dead protoplasm of plants and animals becomes converted into the protoplasm of the living being will be presently fully and correctly ascertained.

The students attending the courses of instruction on the different branches of medical science at the University of Cambridge are becoming year by year more numerous and an increase in the accommodation is absolutely necessary. New buildings are about to be constructed, the total cost of which is estimated at £40,000. New laboratories have been completed at King's College, London, at great expense and were formally opened by Lord LISTER An extremely liberal offer was made to the University of St Andrews by the late Lord BUTE who proposed to found a chair of anatomy in that university and to endow it with the sum of £20,000. The offer, it need hardly be said, was accepted and hearty thanks were tendered to the Marquis of BUTE for his liberality.

The Harveian Oration was delivered before the Royal College of Physicians of London by Dr. CLIFFORD ALLBUTT who took for the subject of his discourse Physiological Darkness before the time of HARVEY and gave a masterly sketch of the course of mingled truth and error in long bygone times.

If the estimate of the quantity of blood in the body given by Dr. JOHN HALDANE and Dr. LORRAIN SMITH is to be trusted, the statement that is to be found in most modern text-books that it equals one-twelfth or one-thirteenth of the weight of the body must be regarded as too high. These observers drew their conclusions from the rate at which the hæmoglobin of the blood becomes saturated with carbonic oxide when a given small percentage of this gas is continuously breathed, and their estimate is that the quantity is only about $\frac{1}{20{\cdot}5}$ of the body-weight, or about seven or eight pounds for a man weighing 150 lb., with extremes of one thirtieth and one-sixteenth. This estimate, whilst it is in accordance with the very marked effects produced in these days by the abstraction of a few ounces of blood, is difficult to reconcile with the estimates of HALLER and WEISBERG, both careful observers, who formed their opinion from the quantity of blood collected from the body in the case of decapitated criminals, and placed it, the former at about from 28 to 30 pounds, and the latter at 24 pounds. Can our better and more varied dietary have led to the production of blood smaller in quantity but of better quality and more adapted to the needs of the economy than the more abundant but less diversified diet of our forefathers?

An interesting lecture on Some of the Mechanisms of the Heart and its Valves was delivered at the meeting of the Chelsea Clinical Society by Dr. WILLIAM EWART. He dwelt upon the presence of a supra-papillary and of a retro-mitral space in the ventricle, showed that during contraction the posterior mitral flap is thrown into pleats, admits a powerful ventricular aspiration, and holds with those who accept a muscular and a valvular element in the first sound. By an ingenious arrangement of reflectors and lenses W. ENGELMANN has been able to exhibit magnified 35 times the action of the living heart of a frog upon a screen. J. A. MACWILLIAM has continued his researches on the physiology of the mammalian heart and discusses the influence of chloroform upon the rate of the heart-beat. Mr. W. H. THOMPSON has studied the effects of the intravascular injection of peptone and albumose, and shows that the vessels of the kidneys and limbs are but slightly affected, whilst those of the spleen undergo moderate, and those of the liver considerable, dilatation coincidently with the fall of blood-pressure. Professor SCHÄFER and Mr. S. VINCENT find that in the extract of the hypophysis cerebri there is a substance soluble in saline solution, but insoluble in alcohol and ether, which when injected into the veins increases blood-pressure, and another substance soluble in alcohol and ether as well as in saline solution which depresses the blood-pressure. The hypophysis cerebri has received attention from other quarters, V. KUPFER having studied its development and H. C. BENDA having read before the Pathological Society of Berlin a paper on its normal structure and pathological condition. The researches of E. V. CYON appear to show that it may supply a deficit of iodothyrin and act as a supplementary organ to the thyroid body. An important research has been carried out by Dr. J. L. BUNCH on the innervation of the muscular coat and the vessels of the intestines. His investigations show that these parts are supplied by the splanchnic nerves, which contain both constrictor and dilator fibres derived primarily from the spinal cord, and that in dogs they leave the spinal cord by the anterior roots of the second to the sixteenth post-cervical nerves, the higher roots containing a larger proportion of dilator fibres, the lower roots of constrictor fibres. Professor STARLING has shown that in the cat as well as in the dog excitation at any one spot of the intestine produces excitation above and inhibition below the excited spot. Dr. F. W. PAVY has followed up his investigations on the sugars in the blood and upon the effects of intravenous injection of various forms of sugar. It is well known that many animals can store up glycogen in the liver when they are restricted to a purely proteid diet. Professor J. SEEGEN, experimenting with liver extract, has found reason to believe that the proteids undergo a disintegration in the liver leading to the detachment of a molecule of a sugar-like substance containing nitrogen which by the action of a liver ferment undergoes further change, terminating in the production of glycogen. Similar conclusions have been arrived at by Dr. BERKHARD SCHONDORFF. On the other hand, two French observers, M. C. BOUCHARD and M. A. DESGREZ, have satisfied themselves that muscle glycogen can be formed in the body from incompletely oxidised fats. The experiments of R. COHN render it probable that glycogen can be derived from leucin and Dr. MARTIN JACOBY points out that there are probably many ferments in the liver. He has himself carefully followed out the characters of a ferment which is capable of oxidising salicyl aldehyde and has given it the name of "aldehydase." An article written by Mr. H. F. BELLAMY and lately contributed to our columns deals with the function of the spleen. It was found long ago by Professor SCHIFF that after ligature of the splenic vessels at the hilum or after removal of the spleen as a whole trypsin fails to appear in any considerable quantity in the pancreatic juice or in an infusion of the gland during that stage of digestion in which, in the intact animal, it is normally present—that is, from four to seven hours after feeding. Hence Professor SCHIFF thought during the congestion of the spleen a substance is produced within the spleen which, carried away by the blood, gives to the pancreas what it requires to form its peptonising ferment. The discovery of the precursor of trypsin, trypsinogen, in the cells of the pancreas by HEIDENHAIN led Professor SCHIFF to repeat his former experiments in conjunction with Dr. HERZEN, and the general conclusion arrived at is that in addition to other functions the spleen furnishes a recrementitious product which causes in the pancreas the transformation of its inert zymogen into active trypsin.

The effects of sudden release from increased atmospheric pressure such as is experienced by those working at the foundation of bridges are well known to be serious and have been attributed to disturbance of the circulatory and respiratory systems. Dr. LEONARD HILL has placed animals under these conditions and finds that with dogs and cats exposed to rapid increase of pressure amounting to two atmospheres and rapid diminution to the ordinary pressure no effects beyond slight increase of the respiratory oscillation and slightly diminished frequency of the pulse occur. The mechanical congestion theory of caisson disease is regarded by Dr. LEONARD HILL as untenable. It would be pertinent to ask how Dr. HILL explains the hæmorrhage from nose and ears that have been observed when the pressure is too suddenly released.

The Croonian Lectures were delivered before the Royal College of Physicians of London by Dr. FREDERICK MOTT, who took for his subject the Degeneration of the Neuron and expressed himself in favour of the view that the terminal arborisation of the axis-cylinder process of one neuron does not anatomically fuse with the cell-body and dendrons of another and that trophically and genetically the two are independent, yet that there is a physiological connexion between adjacent neurons. He also pointed out that the integrity of the sensory moiety of a reflex is almost as important as that of the motor segment; in other words, that sensation must be acute and perfect if the corresponding muscular movements are to retain their delicacy and precision. The second Hughlings Jackson Lecture was delivered before the Neurological Society by Professor HITZIG of Halle; and the lecturer, after bestowing a well-merited eulogium on the work of the physician after whom the lecture is named, proceeded to discuss the subject of the localisation of functions in definite areas of the cortex of the brain. He advocated the view that such centres exist and further contended that in regard to the motor centres two sets might be distinguished, a lower subcortical or reflex set called into play by impressions of hearing, vision, or other special sense, and a higher or cortical set concerned with conscious arbitrary motion.

Dr. A. GURWITSCH has shown that the sheath of SCHWANN of a medullated nerve is genetically an exogenous and quite foreign mesodermal formation. It does not, in the first instance, closely embrace the medullary sheath, but the space between the two is gradually filled up by the growth in girth of the axis-cylinder and of the medullary sheath Dr. W. H. GASKELL, from a comparison of the cranial nerves in mammals with the nervous system in arthropods, finds additional support to his theory of mammalian descent through the arthropods.

Dr. BARBIERI finds that all mixed nerves have more sensory than motor nerves. The ganglia on the dorsal roots belong to the sympathetic system, and in the rabbit there are about 500 cells in each ganglion and about 3000 fibres as it traverses the ganglion.

From experiments with the ergograph Professor MOSSO finds that in soldiers after forced marches the power of the muscles of the arm and hand is diminished, so that, as IOTEYKO observes, whilst moderate exercise of the psychomotor centres produces increased action or activity of both sensory and dynamogenic centres, exhaustion of one centre, as that effecting the movements of the lower limbs, causes depression of all centres and has a tendency to become generalised. He suggests that fatigue is due to some toxin entering the blood current The muscle spindles described as long ago as 1863 by Professor KOLLIKER have been subject to minute examination by Dr. F. PICK. They are fusiform, are surrounded by connective tissue, contain slender muscular fibres with motor end plates, and other thicker nerves, which form a plexus around the fibres and can be shown by degeneration experiments to conduct centripetally. He suggests that they are the receivers and transmitters of the nerve sense.

The origin of uric acid was the subject of an interesting discussion at the meeting of the British Medical Association. The discussion was opened by Professor W. D. HALLIBURTON, and was continued by Professor THOMAS H. MILROY, Dr. ALEXANDER HAIG, and others. The general conclusion appeared to be that it has a double origin, one part being the result of the disintegration of the nuclein taken in with the food, and another part proceeding from destructive changes of nuclein contained in the body, or, as Professor HALLIBURTON expressed it, part is of exogenous and part of endogenous origin. The latter portion is derived from the metabolism of the leucocytes that are so abundantly formed after the ingestion of food.

Several essays have lately appeared on the suprarenal capsules. E. O. HULTGREN and O. A. ANDERSSON in giving the results of a long series of observations and experiments state that extirpation of these bodies in cats and dogs and rabbits occasioned death within a week or ten days. Removal of the organ on one side was followed by the animal becoming thin for a short period. The retention of a small fragment was sufficient to preserve life, but when both are removed death supervenes with great fall of temperature. The metabolism of albumin, the quantity of hæmoglobin, and the number of red corpuscles were not affected. Injections of small quantities of adrenal extract caused temporary improvement, but when large quantities were injected death occurred in rabbits from œdema of the lungs. The injection of extract of the adrenals of rabbits, guinea-pigs, cats, rams, and steers caused rise of temperature in rabbits, whilst the extract of the adrenals of sheep, oxen, and pigs usually caused a fall of temperature. E. BORDIER and H. FRENKEL found that the intravenous injection of very small quantities of suprarenal watery extract caused immediate diminution, or even complete brief and temporary arrest of, the urinary secretion—a condition followed by increased secretion. A very curious inquiry into the effects of light upon general nutrition has been pursued by JUSTUS GAULE He accidentally noticed that the fat bodies situated in the abdominal cavity near the sexual organs in frogs, and especially in winter frogs, are not to be found at night, but are reproduced in daylight. The stimulus to the reappearance of these bodies in daylight is not conducted through the eyes since the phenomenon occurs even after extirpation of the globes.

Publications, &c.

Numerous and valuable articles on Embryology have been published in the *Quarterly Journal of Microscopical Science*, as those of Dr. E W. MACBRIDE on the Amphioxus, of Mr. J. P. HILL on the Embryology of the Marsupialia, of Mr. J W. JENKINSON on that of the Mouse, and on the Nemerteans, by Mr. C. B. WILSON and Mr W. R COE, Dr. A. MASTERMAN on Phoronis, and others, all requiring much care and attention as well as knowledge of the details of microscopical research. The well-written and well-illustrated "Text-book of Embryology" by Dr. JOHN HEISLER of Philadelphia will prove useful to the student as well as to the practitioner Particular parts of the subject have been worked at with care by different men; G. LEVI, for example, has studied the development of the human primordial cranium, C. RABL the development of the lens, E V. WILCOX human spermatogenesis, and G. LOISEL spermatogenesis in the sparrow.

The bibliography for the year in physiology is considerable. Two important cyclopædias have been in course of publication. One of them, edited by Professor SCHÄFER of Edinburgh, who modestly names it a text-book, is just completed. It is written on the lines of the Handbook of Professor HERMANN, the several subjects being committed to the hands of experts. The second is edited by Professor RICHET of Paris and will extend to eight or nine volumes, four of which are now complete. A somewhat similar but less ambitious text-book is appearing in America under the able editorship of Professor W. H. HOWELL of the Johns Hopkins University, Baltimore, assisted by several leading physiologists of that country. The second volume of Professor MORAT and Professor DOYON'S "Traité de Physiologie" has appeared and a well-written text-book has been published by Dr. WINFIELD HALL of the Chicago University. New editions of the Manuals of WALLER, STEWART, and STARLING have been issued and Miss EMMA BILSTEIN has made a good translation of STOHR'S well known text-book of histology.

ANÆSTHETICS.

Intra spinal Cocainisation and Interstitial Infiltration.

Among the year's events in this department of medical science may be placed perhaps first in order, but rather on account of their novel development than of their intrinsic merit, the introduction of spinal cocainisation as a definite mode of producing analgesia, and the extension of local anæsthesia by interstitial infiltration. To **LEONARD CORNING**, an American physician, must be accorded the initiation of the suggestion (1885) that an extended anæsthesia would follow the injection of local anæsthetic bodies into the sheaves of nerves or of the spinal cord itself. **BIER**, in his original monograph in 1899[1] put **CORNING'S** suggestion to the test of actual trial and employed the lumbar puncture. The tissues were infiltrated down to the vertebræ (**SCHLEICH'S** method) and a plugged needle (**QUINCKE'S** plan) was introduced into the spinal canal, some cerebro-spinal fluid was removed, and from 0·005 to 0·01 gramme of cocaine in solution was introduced. The analgesia appeared in from five to eight minutes and persisted in one case for 45 minutes. **BIER** reported more or less severe after-effects—headache, vomiting, depression, and rise in temperature. Besides the obvious danger of sepsis which **BIER** and others insist can be avoided there have been during the past year numerous grave complications and some deaths following this method of producing anæsthesia. **BIER** himself, writing in the *Munchener Medicinische Wochenschrift* of Sept. 1st, 1900, warns the profession against the wholesale adoption of the method, since he regards our knowledge of it as being at present too vague for its safe adoption except in certain cases. Serious accidents, he says, follow injections of five milligrammes and less Under no circumstances does he permit more than 15 milligrammes. The method was discussed at some length at the Surgical Congress in Paris, and several speakers who were in favour of it yet admitted that deaths had followed intraspinal injections of cocaine (**PHELPS**). **TUFFIER**[2] has published 125 cases, including 58 laparotomies, of lumbar puncture made between the fourth and fifth vertebræ. Although he has gained a fairly wide experience and has performed a large number of operations he has been unable to eliminate more or less serious complications, such as vomiting which commonly commences soon after the injection and is often very severe, pallor, respiratory distress, headache, nearly always present and lasting from 15 to 24 hours, persistent paresis and rise of temperature. Out of 125 cases five deaths resulted, and although he exonerates the anæsthetic in four cases he states that the fifth patient died with symptoms of asphyxia. Many observers also have recorded cyanosis as a common symptom. **RACOVICEANU-PITESCI** and **SEVEREANU** of Bucharest have used the method largely and they refer to two deaths in Roumania as a direct result of it and to several serious complications and sequelæ. The former surgeon records 80 cases of cocaine toxæmia persisting for four or five days, while in three cases artificial respiration and stimulants were called for to save life. **SEVEREANU** likewise reported that he had met with great exhaustion and prostration which lasted for some days after injection. He used from one to four centigrammes. He regards the method as being unsatisfactory in that the patient witnesses the operation on his own person. Besides these undesirable accidents associated with this method **GUMPRECHT**[3] has published 17 cases in which lumbar puncture independently of the use of cocaine has been followed by dangerous conditions due probably to the operation. **HENNEBERG** and others have met with medullary hæmorrhage from the same cause. Various writers speak of the difficulty of getting the needle into the canal arising in some cases, especially in those in which the vertebræ are displaced or rigid. The method has also been used extensively in the United States and isolated observers have reported successful cases without dangerous symptoms. S. **ORMOND GOLDAN** met with vomiting in half of his 20 cases; the patients were first pale, then flushed. Headache was present in 50 per cent., and some rise of temperature and profuse sweats were also observed. Rigidity of the muscles of the back occurred in three patients, a troublesome symptom, which in one case persisted for a week. In three instances analgesia was never obtained.

Cocainisation in Parturition.

KREIS[4] was one of the first to use cocainisation of the spinal canal in obstetric practice. According to this observer the analgesia in his cases lasted two hours and the cocainisation did not interfere with the functions of the uterus. **MARX**[5] has recorded a series of cases of parturition without mishap. In these he obtained analgesia by injecting cocaine by the lumbar puncture. His experience with eucaine went to show that it was unsatisfactory for intra-spinal injection. He has also employed morphine, but in one case severe toxic symptoms followed it; he now advises that hydrobromate of hyoscine ($\frac{1}{200}$th grain) should be injected hypodermically in order to relieve the nausea, headache, and vomiting which he finds incidental to the puncture and spinal cocainisation. The statement that "there are frequent nausea, vomiting, severe headache, profuse perspiration, chilly sensations, temperature up to 102° and 103°" is not encouraging. **MARX**, whose careful paper deserves attention gives details of a number of cases. An obvious objection to intra-spinal cocainisation is insisted on by **MATAS**. It is that if the first injection fails to produce a sufficiently prolonged analgesia re-injection is, in obstetric cases, practically impossible. He limits the methods to adults, and to "reasonable persons" who have good self-control, when regional infiltration is impossible, to persons suffering from bronchitis, emphysema, or who for other reasons cannot take a general anæsthetic, and lastly, only to cases which can be completed in an hour and a half. A large number of papers dealing with intra-spinal cocainisation, giving more or less full reports of cases, have appeared since **BIER'S** first monograph, and although the writers make light of the adverse symptoms, which they impute to any cause other than the obvious one, **BIER'S** caution seems more than necessary. Communications of especial note dealing with the subject have appeared by **FOWLER**[6] (New York), **ORMOND GOLDAN**,[7] and **MARX**,[8] and a study of these papers confirms the statements made above. It is interesting to remark that among **FOWLER'S** cases several instances are reported in which analgesia could not be obtained. **NICOLETTI'S** (Naples) experiments on rabbits and dogs must also be referred to in this connexion. Intra spinal injections of cocaine according to this observer produce no histo-pathological change in the nervous tissues—a fact which led **NICOLETTI** to believe that the analgesia is the result of vaso-motor effects consequent upon the action of such bodies as cocaine, ergotin, antipyrin, and quinine. Similar evidence of the immunity of the nervous structures was given in the necropsy of a patient published by **SELDOWITSCH**.[9] The patient died from cachexia. **SELDOWITSCH'S** cases all showed some of the symptoms described by most writers on this subject, while **BIER'S** first experience[10] was more favourable.

Neuro-regional Analgesia.

An attempt has also been made to produce "neuro-regional analgesia": (1) intra-neural, by injecting the cocaine into the large nerve-trunks supplying the region to be operated upon; or (2) para-neural, into the tissues about the nerve-trunks.

OBERST, KROGIUS, BRAUN, and KUMMER follow this method. MATAS, whose paper is referred to above, gives careful directions about these modes of producing analgesia in these ways, and to his writings we must refer our readers. SCHLEICH'S important work, "Schmerzlose Operationen," issued recently, gives a very fair account of the case for local analgesia, although it must be admitted that his method leaves much to be desired if true immunity from pain is aimed at. BARKER of University College Hospital has in our columns given his pronouncement in favour of eucaine β and has apparently been satisfied with his trials of local analgesia, using BRAUN'S modification of SCHLEICH'S original method.[11] CUSHING[12] reports a number of herniotomies done under local analgesia. In cases in which a general anæsthetic is undesirable infiltration with eucaine or cocaine is, he considers, most valuable. The patient is, he reminds us, however, longer under operation and feels pain to a certain extent.

Miscellaneous.

Some valuable work dealing with the physiology of the action of anæsthetics has been undertaken during the year. Experiments by Professor W. H. THOMPSON of Belfast appear to show that while ether and its mixtures give rise to an increase in the urinary water secreted, and of the total nitrogen per hour, chloroform brings about an opposite result. Chlorides were lessened under all anæsthetics. While chloroform caused glycosuria albuminuria was absent. KEMP and THOMSON, to whose experiments we have referred elsewhere in our columns, came to a conclusion which if confirmed would seriously affect the reputation of ether as a safe anæsthetic. Investigating the subject anew from the clinical as well as the experimental side DUDLEY BUXTON and A. G. LEVY have shown that the results arrived at by preceding workers were not in their entirety reliable since they had mistaken the effects of ether toxæmia for a normal "ether effect." This ether toxæmia never occurs in practice and in experiment only when the inhalation is conducted on very dangerous lines. The results arrived at by the last-named observers are extremely important but can only be mentioned briefly. Suppression of urine as a result of ether inhalation does not occur, albuminuria is extremely rare, and clinical evidence that they advance revealed that renal after-effects ensuing upon etherisation even when the kidneys are antecedently diseased are very rare. "Ether," they say, "should still be regarded as a very safe anæsthetic." Their experiments with chloroform are also of interest. The respiratory after-effects of ether formed the subject of an important discussion by the Society of Anæsthetists. The conclusion which, it appears, may be fairly drawn from it is that much confusion has arisen in the recording of cases; the anæsthetic, although occasionally at fault, but far less often so than is commonly stated, is in most instances one of many factors bringing about the pulmonary complication. A point advanced by MAYO ROBSON, and confirmed by others, being that in private practice respiratory effects are almost unknown, while in hospital practice, under less favourable conditions, pneumonia or bronchitis occasionally supervenes after operations undertaken under ether, J. FREEMAN, speaking before the Bath and Bristol Branch of the British Medical Association,[13] stated that out of 3000 etherisations in which persons of all ages were included he had only met with two cases of bronchitis.

MCCARDIE has recorded[14] a rare complication under ether—viz., spasmodic closure of the larynx—and a somewhat similar occurrence is reported by SHUTER in which respiration failed under ether. FEILCHENFELD'S[15] suggestion to give small doses of tincture of strophanthus (from five to six minims) on two nights before giving chloroform in cases of asthenic or excitable hearts is supported by carefully thought-out reasoning. WALKER (Durazno, Central Uruguay) has used anal injection of artificial serum in a case of chloroform collapse with success, but the rationale is not easy to grasp As chloroform was given by the towel method it seems perhaps better to leave off using the towel, and so to avoid the necessity for employing the artificial serum. H. A. HARE, whose name is associated with much valuable experimental work dealing with the physiology of anæsthesia, has delivered a valuable address on anæsthetics in which he reiterates his view that chloroform accidents arise from vaso-motor paresis.[16] KRAMER'S[17] experimental investigation of the influence of stimulation of a sensory nerve on circulation and respiration under complete, and under incomplete, anæsthesia brings our acquaintance with this subject within the region of exact knowledge. His conclusion is that severe vaso-motor shock is more liable to follow operations done under partial anæsthesia than such as are done under complete insensibility. The method of massage of the heart which is called "Prus's plan," although successful according to Dr. PRUS in 76 per cent. of dogs which he poisoned with chloroform until cardiac action failed, was tried by him on a person who committed suicide, but without success. Dr. PRUS removes the rib cartilages and opens the pericardium. The measure, an heroic one, may have failed in this case because the person was an alcoholic subject whose heart muscle was probably past stimulation.

Mishaps under Anæsthesia.

We have repeatedly drawn attention to casualties under anæsthetics and have indicated the obvious lessons to be drawn. It is matter of regret that during the year many fatalities under chloroform have occurred, and too frequently in cases in which nitrous oxide, ether, or the A.C.E. mixture might have been more safely employed. The practice of giving chloroform in dental cases is one too obviously bad to need argument, and yet we have had again and again to report deaths arising through it. We may hope that in the new century wiser counsels may prevail. We also hope that the necessity for the better teaching and equipment of our hospitals in matters connected with anæsthetics, to which we referred recently in a leading article, may receive the recognition which it undoubtedly deserves.

No special advance in methods or apparatus has to be recorded for the year 1900, but a pronouncement by the General Medical Council that any medical man giving anæsthetics for a dentist who was not on the Dental Register would be liable to have his conduct investigated by that body is a noteworthy one for all anæsthetists.

MIRROR OF HOSPITAL PRACTICE.

The "Mirror of Hospital Practice" has during the year contained descriptions of many interesting and important cases from the hospitals of the metropolis and the provinces, and in some instances from the hospitals of our colonies. These cases serve to illustrate the treatment of the present day as carried out in these institutions and they may be taken to represent the present high level which surgical science has reached.

The best treatment of intussusception cannot yet be considered as finally determined, for some surgeons are still of opinion that laparotomy should always be preceded by an attempt at reduction by injection or inflation. It is certain that either of these procedures may, if performed skilfully, be carried out without any real addition to the risk which the patient incurs, and certainly reduction sometimes occurs under this treatment. But in the majority of cases these attempts end in failure, and it is then necessary to submit to the shock of an abdominal section a child who has already been weakened by these procedures. If the laparotomy be performed only a few hours after the commencement of the intussusception a very small incision is needed, the reduction is quickly performed, and the shock is minimised. These remarks are illustrated by the cases that have appeared in the "Mirror." Dr. H. A. LEDIARD of Carlisle recorded two cases—one a child two years and five months and the other only six months of age. In each case attempts had been made to effect reduction by injection. Laparotomy was performed and both children recovered. Mr. HARRY LUPTON of Stratford-on-Avon operated on an infant, aged 10 months, who had the symptoms of an intussusception, and though great difficulty was experienced in reducing it the child recovered. In this case the operator was convinced from the tightness of the invagination that nothing short of laparotomy would have been of any avail. Mr. J. HOWSON RAY has recorded four cases in which he has operated for this condition. All the children were under the age of nine months and two recovered and two died. The two successful cases had lasted 12 hours and two days respectively, but the two fatal cases had lasted two and a half days and five days respectively, and in one of them it was found necessary to resect a portion of the bowel. Two interesting instances of this condition were recorded by Mr. LAWFORD KNAGGS of Leeds; in one a child, aged three and a half months, had a primary, a secondary, and a retrograde intussusception. In the other case the invagination was caused by a lipoma of the bowel.

Another subject which has been well illustrated in the "Mirror" during the past year is the antitoxin treatment of tetanus. The value of the antitoxin is only marked if it is given early before any large amount of toxin has been absorbed, and therefore its use is often very disappointing, but the antitoxin in moderate doses may be administered without danger, and therefore it may always be given; yet its employment should not prevent the other surgical treatment of the wound by which the continued absorption of toxins from the wound may be prevented.

The operation of total removal of the upper extremity, interscapulo-thoracic amputation, or Berger's operation as it is often called, is by no means frequently performed, but we have been able to publish the notes of two cases in which it was found necessary. The first case was under the care of Mr. T. J. VERRALL and the operation was performed for a sarcoma of the upper end of the humerus. No recurrence had taken place 22 months after the accident. The other case, which was under the care of Mr. EDMUND OWEN, was one in which after a very severe burn the whole arm and a part of the mammary region were entirely destitute of skin. The arm was perfectly useless, as apparently the muscles were affected. Local applications and skin graftings were of no avail, and it was therefore determined to remove the limb, and there was not sufficient covering for any amputation lower than the interscapulo-thoracic The patient recovered rapidly from the operation, and was well two months later.

Foreign bodies are by no means rarely found in the bladder, and they are probably much more frequently met with in the female bladder than in the male bladder, and this is due to the fact that the urethra in the female is much shorter and wider than in the male. One of the most curious examples of foreign bodies in the bladder was in a case under the care of Mr. J. H. MORGAN. A woman, 32 years of age, complained of symptoms pointing to a vesical calculus, and when she was sounded a stone was found and Mr. Morgan decided to perform lithotrity. When the stone had been crushed and the fragments were being washed out it was found that there were several bits of glass and globules of mercury amongst them. Some larger portions were removed by means of forceps and they were seen to be parts of a clinical thermometer. No history could be obtained of the introduction of the instrument. An interesting case was recorded by Mr. T. F. CHAVASSE, in which the husk of an oat made its way probably from the larynx to a situation under the skin of the neck whence it escaped after an incision had been made over it. Mr. CHAVASSE has also described another case of a foreign body; a little girl, three years old, swallowed a brass shawl pin, two and a half inches in length. Two months later it was removed from the abdominal wall a little below and to the left of the umbilicus. At Guy's Hospital under the care of the late Mr. J. N. C. DAVIES COLLEY was a woman who seven months previously had swallowed a packing-case needle, four inches long. She had had at intervals attacks of severe pain on the left side of the abdomen, where a tender firm swelling developed. This was incised on two occasions. On the second operation the peritoneal cavity was opened and the needle was found in the descending colon, whence it was removed, and the patient recovered.

Thrombosis of any of the mesenteric vessels is a very rare cause of intestinal obstruction, and two cases have been recorded in the "Mirror." In one case, under the care of Mr. C. WHIPPLE, a man, 38 years of age, had 38 inches of the ileum which were deeply congested and in part gangrenous, the result of thrombosis of its mesenteric vessels. The symptoms produced were suggestive of obstruction but none could be found on operation and therefore an enterostomy was done but the patient died a few hours later. The other case was that of a man, 51 years of age, who died seven hours after he was admitted into St. Pancras Infirmary under the care of Dr. W. M. DUNLOP. He suffered from vomiting and was much collapsed. At the necropsy it was found that about two feet of the ileum were intensely congested and that the mesenteric veins corresponding to the congested bowel were thrombosed. No cause for the thrombosis could be discovered.

The blocking of the pelvic cavity by a tumour is an exceptional reason for the performance of Cæsarean section. In a case under the care of Dr. LLOYD ROBERTS of Manchester a fibroid tumour of the uterus was discovered at the commencement of labour. As only one and a half inches of available conjugate were left it were decided to perform Cæsarean section. The child lived and the mother also, though she had an acute septic attack which was apparently benefited by the use of anti-streptococcic serum. In another case Cæsarean section was performed in a case with some contraction of the pelvis and the foot presented with the head. The child was dead at the time of the operation, but the mother made an almost uninterrupted recovery.

Mr. D'ARCY POWER had an interesting case under his care at St. Bartholomew's Hospital. A man was admitted into the hospital for total suppression of urine, and though an examination was made of the right kidney no stone could be found, and the man died next day. At the post-mortem examination it was found that the left kidney was represented by a small thin piece of fibrous tissue, but a pervious ureter was present. The right kidney contained four small calculi, and the right ureter was patent.

An instance of compound separation of the lower epiphysis of the femur has been recorded by Mr. E. W. ROUGHTON. It occurred in a little boy, nearly six years old, who caught his legs in a wheel of a cab behind which he was riding. A portion of the shaft of the femur necrosed and had to be removed, but the boy recovered with only about half an inch of shortening. The other femur was fractured at the same time and it united well.

Dr. EDMUND CAUTLEY has recorded one more case of the rare condition which has been named "congenital hypertrophic stenosis of the pylorus." Up to the present 32 cases of this curious condition have been described and 26 of these have been put on record within the last five years. The case was a fairly typical one, though, in place of the constipation which is usually present there were watery motions. The child, who had had vomiting constantly from birth, died on the day after admission to the Belgrave Hospital for Children, so that there was no time for treatment. Up to the present time only one case of recovery has been recorded and that was operated on, so that in the future an early operation seems to offer the best chance of recovery though the patients are hardly in a very suitable condition for operation.

In this country hydatids are by no means common, but we have recorded several in the "Mirror." In one case under Mr. RUTHERFORD MORISON there was one hydatid cyst in the liver and one also in the lung. In a man under the care of Surgeon F. H. A CLAYTON, R N., the diagnosis of hydatid of the liver was made by the discovery of daughter cysts in the motions. The patient suffered from symptoms resembling those caused by the passage of gall-stones along the bile-ducts. The symptoms all ceased after a time and the man apparently recovered without any operation.

Duodeno-choledochotomy is a name applied to the rare operation by which a gall-stone impacted at the termination of the common bile-duct is removed by opening the duodenum and then incising over the stone. It has been done in about 15 cases, with three deaths. Mr. FREDERICK PAGE successfully performed this operation on a woman, 59 years of age, who had been jaundiced for three months.

THE NAVAL AND MILITARY MEDICAL SERVICES.

The War in South Africa.

When summarising at the close of last year the events falling during the twelvemonth under this heading we wrote under circumstances of great gloom, for it was during the dark early days of the war in South Africa. Looking back on our articles during the first stages of the campaign there is a melancholy sort of satisfaction in finding that we expressed the opinion that the war would prove a much more formidable undertaking and would require a larger force than was generally imagined, although we had then no idea, of course, that it would prove so costly and formidable as it has done. But the state of matters in South Africa, if still unsatisfactory, is nevertheless different now from what it was then and during the beginning of the present and now closing year. Then it was the story of unpreparedness on our part, of insufficient and divided forces, beleaguered garrisons, and invaded territories. The fortitude and determination of our generals and the courage and determination of our troops enabled them to hold their own—and more, while the enemy, from want of a bold and original strategical scheme, missed their grand opportunity. Then Lord ROBERTS came on the scene with forces adequate to the emergency, and a speedy change occurred in the complexion of the campaign. Our misfortunes were retrieved everywhere Our soldiers have had to fight under altogether exceptional conditions created by the recent improvements in arms and ammunition such as no other troops have ever yet had to encounter and against an alert and stubborn foe with a perfectly new system of tactics. They have acquitted themselves well.

If Paardeberg was, militarily speaking, the turning-point of the campaign, immediately afterwards came, as far as the medical services were concerned, the overwhelming difficulties of the war. Up to that time there can be no doubt that the medical arrangements were the bright spot of the campaign. The weight of skilled, expert, and independent testimony—that, for example, of Sir WILLIAM MAC CORMAC, Mr. FREDERICK TREVES, and numerous others—was all to the same effect. The sudden and wholesale outbreak of enteric fever in a fatigued army, which had altogether outmarched its supplies and had not the necessary transport to bring them up promptly, will most probably, in our opinion, be found to account for the deplorable occurrences which temporarily obtained.

The prevention of the diseases incidental to war and the care of the sick and wounded during a campaign have always been, and, despite all we can do, will probably always continue to be, a very difficult problem for practical solution. As medical science advances and a growing feeling of patriotism and philanthropy on the part of the nation finds its expression in providing more and more admirably equipped hospitals, appliances, and organised aid, so must it become more and more difficult for a Government to compete successfully with outside efforts and to keep pace with the increasing demands of a luxurious age. The British Empire has possessions and interests everywhere and we are always engaged in some war or other, but no two of them are exactly alike or resemble the wars of other European Powers. In South Africa we have had to fight physical geography as well as a stubborn foe, and it was the former which caused the temporary collapse of our arrangements for the care of the sick. We need not enumerate the number and names of the civil hospitals and hospital ships which have been sent out to the seat of war. They have vied with one another in their attempts at completeness of plan and detail. The land service hospitals have been designed and fitted out—from an administrative and scientific point of view—with an elaboration of comfort and convenience which, considering their purpose and work, left little or nothing to be desired. The national movement in aid of the sick and wounded in war is one which deserves every support and encouragement. In any large war civil aid is now necessary, for no Government can, with the means at its command and by purely official methods, successfully cope with modern requirements. And in any case voluntary aid societies and organisations can render very effective help in supplementing the provision made by Government. As far as Government and the military authorities are concerned they can never lose sight of the fact that armies exist for the purpose of fighting and that they fight to win, and that, consequently, everything has to be subordinated to military success. The aims and objects of all field service medical regulations are to secure a due provision and proper distribution of men, material, and transport. The pivot of the whole system is to free the movement and action of a fighting force as far as possible, by dispensing with all needless reduplication of stores and appliances, and by relegating the sick and wounded in the direction which they must eventually take, if they prove inefficient—namely, to the hospitals in the rear, where they can be properly attended to Some sort of medical equipment for war has to be provided and maintained by Government on a uniform and suitable scale and it must be more or less adapted for any occasion that may arise and must be supplemented to meet special requirements. As no limitations are imposed upon philanthropic sources of supply, either in aim or object, it is obviously unfair to compare them with the Government supplies. Taking the modern system of field medical service as a whole it is based upon thoroughly sound principles, but it must be capable of being modified and adapted to circumstances if it is to prove effective. Sometimes it is extremely difficult to do this. The conditions in connexion with the war in South Africa were quite exceptional and may never occur again. Our army was fighting some 7000 miles away from England and over an area of about 160,000 square miles of territory with long and frequently interrupted lines of communication. There was a favourable combination of circumstances from a medical point of view nearly up to the capture and occupation of Bloemfontein. The battles were fought close to railroads and the British army was healthy. The time of stress and strain which was to test the efficiency of the army medical service had not arrived. But it came when the army had outmarched its supplies and when an outbreak of enteric fever followed on the insufficiency or breakdown of the transport. Then it became obvious. Undoubtedly all the circumstances were terribly against the medical service, but the fact remained that the hospitals and medical supplies were wanting.

The Medical Services of the Present and Future.

It is impossible for financial reasons to maintain in time of peace a Royal Army Medical Corps at a strength and on a scale adequate for the requirements of a big war. That the corps as it exists at present must be largely increased and that its officers must have increased facilities for professional study and training is obvious. The way in which this can be best accomplished must be considered hereafter. A radical and comprehensive reorganisation will be necessary for the purpose. But some scheme in the nature of the German system of keeping the civil medical element in touch with the army will also have to be introduced, as well as a method of welding all branches of the medical service—militia and volunteers—with the regulars and of giving all their members some training in military medical duties. The war in South Africa has opened a new chapter in the history of the British Empire by closely cementing the colonies with the motherland; and we have now to frame an organisation by which the whole strength of the medical element at our disposal can be made available in war. The aim in our future wars will rather have to be to take the hospital to the wounded than the wounded to the hospital. The field hospitals will require to be treated as independent units in every respect and to be furnished with adequate transport; and the bearer columns will probably have to be attached to, and utilised by, these hospitals. A more easy-working and active organisation will also have to be given to stationary hospitals to enable them to change their position and to move when and where they are required. The hospital nursing system will have to be largely increased and better provided for; but we do not believe that it is practicable or expedient to have female nurses with the moveable hospitals in the immediate track of the front fighting line. As regards the men of the Royal Army Medical Corps, it has always seemed to us that every attention should be given to their hospital training as orderlies and nurses, and that their military training in the way of parades and inspections should be curtailed as much as possible. The usefulness of such men lies in the former direction—as properly qualified attendants on the sick and wounded—and not in their acquaintance with military drills or their smartness as soldiers. The question of the organisation of a special service with a large sanitary executive for the carrying out of practical army hygiene will have to be considered and settled. There is much besides—such as having an army medical school in London instead of at Netley—affecting the medical service and all that appertains thereto which will have to be taken up in earnest in the coming army reforms, but whatever is done must be done deliberately and in time of peace.

Some Lessons of the War.

The feelings of disappointment and depression caused by the publication of Mr. BURDETT-COUTTS'S letter in the *Times* reflecting upon the medical arrangements for the care of the sick and wounded will not easily be forgotten. Debates ensued in the House of Commons, and these were followed by the appointment of a Royal Commission, which proceeded to South Africa to investigate all the facts on the spot. The publication of the report of this Royal Commission has still to take place, and until this report sees the light it is best not to dogmatise hastily upon the subject.

The same may be said of the whole history of the war. The official report has yet to be prepared, and until the country is in full possession of facts judgment is premature. We have, however, had the gratification of being able to supply the readers of THE LANCET with a large and varied amount of information concerning the war. The use of the newest rifled weapons and modern projectiles has revolutionised many of our views about gunshot wounds and military surgery. The Mauser and other bullets of a similar kind are, happily, merciful missiles as regards the character of the wounds which they inflict, and the results have often been of a very remarkable character, constituting a revelation to surgeons as to what the human body can tolerate with relative impunity. Antiseptic surgery has, it is needless to say, been universally practised and with splendid results. The climate also was very favourable, and, as a rule, the atmosphere was clean, dry, and aseptic. Our thanks are due to Sir WILLIAM MAC CORMAC for his admirable and descriptive series of articles, while our readers are also indebted to a number of other contributors and correspondents for first-hand news from the seat of war. Many of the medical officers of the navy as well as those of the army and the Colonial forces—to say nothing of many distinguished hospital surgeons and others—have taken part in the campaign.

We cannot leave the subject of the war in South Africa without adverting to the spirit of patriotism, devotion, and self-sacrifice which it has evoked on the part of the medical profession, both civil and military. On no previous occasion has such an array of surgical and medical skill and ability been brought to bear upon field service work in coöperation with the regular military medical service. As regards the latter, it would be impossible to name all the medical officers deserving of mention. One and all, military and civil alike, the medical men in the Boer war have distinguished themselves by their arduous and cheerful service. Nor have they been behind the combatants in personal gallantry, and here we may be permitted to mention two names. As a sample of bravery and devotion the way in which Major W. BABTIE of the Royal Army Medical Corps won his Victoria Cross has never been excelled. The second name is that of an officer of the Colonial medical service. Captain ALBERT T. DUKA of the Queensland Army Medical Corps was the only medical officer shut up with the small force during the siege and successful defence of Elands river camp from August 4th to 16th. The exploit of the force is comparatively little known, or at any rate has not commanded the attention that has been given to many less striking episodes in the war. The besieging army was a large one commanded by General DELAREY, who continuously shelled and fired on the camp and succeeded in beating back General CARRINGTON'S relief force. The Elands river camp garrison lost heavily. There were 73 casualties out of a small force, and five men (besides a hospital orderly) were wounded a second time in the hospital extemporised for the occasion. The pluck and endurance shown by Captain DUKA were conspicuous, and the professional services that he rendered on the occasion were of an exceptional kind performed under very trying circumstances.

The Naval Medical Service.

A good deal of work has fallen upon the Naval Medical Service during the past year. The medical officers of that service have taken a distinguished part in connexion with the naval brigades both in South Africa and China. In the former they were present, of course, at the siege of Ladysmith. Members of the service were also with Lord METHUEN'S force and took part in the operations under that general, several of them being mentioned in dispatches for their meritorious services. In the war in China the officers of the Naval Medical Service played a very responsible and important part in connexion with the relief force under Admiral Sir E. H. SEYMOUR.

The Indian Medical Service—the Indian Contingent for China.

As regards the Indian Medical Service we may say that the pressure upon the officers of that service has been great during the past year, owing to the continued prevalence of plague and famine and epidemic cholera and other diseases which are incidental to India. The very serious and critical state of affairs in China has, moreover, thrown upon the medical authorities of India the duty of making all the medical arrangements and the fitting out of a large hospital service for the expeditionary forces (mainly composed of the native army) to take part with the composite international forces of other Powers in the operations in China. From all we can gather we do not think that either the Indian or the Imperial Government has had practically much to learn from the other great military Powers in the fitting out and conduct of such expeditions or of the hospital services or provision of transport in connexion therewith. If the same amount of criticism had been brought to bear upon the conduct of affairs in China that has been applied in South Africa it would be found that this country has held its own. It seems, according to late reports, that the health of the German, and of our Indian, troops in China is bad. It is becoming very cold there, and as the Sikhs and native soldiers from India always feel the cold very much and are liable to acute pulmonary affections and recurrences of malaria fever at this season an increased amount of sickness among them is only what might be anticipated.

Ashanti.

The trouble in Ashanti must not be left without mention. From a medical as well as a military point of view the punitive expedition was a success, for, considering the unhealthy nature of the climate, the unfavourable seasons, and the hard work and exposure, it was attended with a relatively small loss of life. This is partly to be accounted for, no doubt, from the fact that mainly native forces inured to the climate were employed.

It will be seen from the foregoing that the history of the public medical services during the year 1900 has been almost entirely one of war. Let us hope that their history in 1901 may be one of peace and progress.

CHEMISTRY.

Radio-Activity.

Perhaps the phenomenon in chemistry which has attracted most attention and study during the year has been that comparatively newly-discovered property of certain substances which is now called "radio-activity." It would seem that there exists a group of elements which manifest radio-activity to a marked degree. Thus a new and most fascinating field of inquiry has been opened up since M. HENRI BECQUEREL observed that compounds of uranium in particular emit rays which affect a sensitive photographic plate through bodies usually considered opaque to light, and further that these radiations are deflected by a magnet and cause the discharge of an electrometer when brought to bear upon it. These rays have consequently so far been called "Becquerel rays" or uranic rays. But these rays appear to be emitted by other elements. Their discovery is next in importance to Professor ROENTGEN'S discovery of the rays which still have to be called "x," for it is announced that the study of radio active substances has laid bare new elements. Recent investigations would appear to show that radio-activity is due to an element or elements not yet isolated. Up to the present it is said that uranium and thorium compounds alone are practically active—that is to say, that the property of emitting rays which act on photographic plates is assumed to be a specific property of uranium and thorium. Sir WILLIAM CROOKES in a number of very interesting experiments which he has made has shown that amongst the minerals which he employed for the purpose those that were radio-active contained either uranium or thorium. In regard to uranium Sir WILLIAM CROOKES has obtained evidence which tends to show that the supposed radio-activity is due to the presence of a foreign body and is not an inherent property of the element itself. For the present, therefore, the unknown body must be provisionally UrX. The question remains as to whether in thorium compounds the same body exists. Already some investigators in Paris believe that they have obtained distinct evidence that this high degree of radio-activity is due to a hitherto unknown element. A substance has been isolated which has since been called "radium," the properties of which, it is said, resemble those of pure barium. It possesses, however, a higher atomic weight. Later it was announced that by mere contact of this substance with a salt of barium its radio-active property was communicated and thus an artificially radio-active barium was obtained. It is evident that chemists are on the threshold of an entirely new field of research which promises to yield very remarkable results. The position at present appears to be that we know of radio-active bodies which have five different origins—the compounds of uranium, thorium, polonium, radium, and a substance resembling titanium. Uranium and thorium have, of course, been long known as well defined chemical bodies, but the three last-named are so far only hypothetical elements. Of these radium is the best known, because greater study has been devoted to it.

The Transmuting of Elements.

The question of transmuting the elements has once more arisen, but this time attention has been turned not to the conversion of copper into gold, but to the conversion of phosphorus into arsenic and possibly antimony. As is well known, these elements are very "near relatives." The crux was, what was the black substance known as black phosphorus present in ordinary phosphorus after the addition of ammonia. It was suggested that it was arsenic produced by the action of ammonia on phosphorus. It has since been declared by Mr. T. FITTICA that he has, by acting upon phosphorus with ammonia in the presence of air, obtained a true transformation of phosphorus into arsenic, and according to his view the latter would appear to be a compound of phosphorus with nitrogen and oxygen. Later, the same investigator has stated that he has succeeded in transmuting phosphorus into antimony. These statements, one and all, are generally discredited, though, of course, the creed is fast gaining very general adherence that there is but one element, a primordial "stuff" out of which the rest of the elements have been and perhaps are being, elaborated. Whatever may be the truth in regard to these averred transmutations it is remarkable that quite recently it has been shown that arsenic may be administered in the form of a methyl compound—namely, cacodyl—in comparatively large quantity with relatively slight toxic results. Further, cacodyl is said to be almost a specific in debilitated conditions, replacing the phosphorus in nerve tissue. Does it replace phosphorus or is it arsenic transmuted into phosphorus?

Argon and Company.

Professor W. RAMSAY and his colleague Dr. M. TRAVERS have been busy studying the curious companions of argon.

So far argon would appear to be associated with three other elements called respectively "neon," "krypton," and "xenon." The place of these newly-discovered elements in the chemical hierarchy is still surrounded with obscurity, although they show a regularity in some respects which admits of their classification in the periodic code. But apparently there is little that is analogous between them, so that the properties of one do not necessarily suggest the properties of another. With the ordinary elements, as is well known, it was possible to predict by analogy the properties of an element yet undiscovered and missing in the periodic arrangement. There is, of course, a grand truth at the bottom of the periodic law but as yet this system of classification, it must be confessed, is still a conundrum. A gas apparently simulating argon was obtained by Dr. T. L. PHIPSON by passing dry cyanogen through a red-hot tube full of iron nails. The gas appears to be a carbide of nitrogen, but the announcement seems to have received little attention and certainly, up to the time of writing, no confirmation.

The Production of Ozone.

An interesting method for the production of ozone has been discovered by M. HENRI MOISSAN, who has shown that when fluorine comes into contact with water at a low temperature hydrofluoric acid is formed together with ozone. The case is one of polymerisation of oxygen which, of course, in the first instance is liberated by the fluorine. The method is not expensive and the ozone obtained is concentrated, and it is possible that this reaction may be of advantage for the commercial preparation of ozone.

Lotus Arabicus and Prussic Acid.

The production of prussic acid in nature has been well exemplified in the case of the *lotus Arabicus*, a small leguminous plant indigenous to Egypt and North Africa. Mr. WYNDHAM R. DUNSTAN found that when moistened with water and crushed the leaves of the plant evolved prussic acid in considerable quantity. The plant has proved highly poisonous to horses, sheep, and goats, and has been a source of anxiety to the military and civil authorities in Egypt. In the course of the investigation a new glucoside was recognised.

Desiccated Albumin.

Some interesting observations on the effect of desiccating albumin upon its coagulability have been made by Mr. J. BRETLAND FARMER. By carefully drying albumin this substance appears to be brought, so to speak, into a static condition. Chemical change or physico-chemical change is inhibited just as in an interaction between phosphorus and oxygen when conditions of complete dryness obtain. Similar conditions may be regarded to obtain in the case of protoplasm or micro-organisms which, when sufficiently desiccated, withstand conditions which otherwise would certainly promote chemical disintegration. "They—that is, the seeds and spores of certain bacteria—appear to be reduced to a static condition by drying, and the researches of ROMANES indicated no measurable chemical change as proceeding in them under these circumstances; and, again, the investigations of BROWN and ESCOMBE and of Sir W. THISELTON-DYER have also rendered it difficult to believe, when subjected to the other end of the scale of temperature, that any metabolism can really be proceeding. In these cases the molecular machinery of life is all present and intact, but the manifestation of vitality as measured by chemical movement and by the change in the condition of energy is absent. But such a state differs widely from death, seeing that when the conditions favourable to the continuous progress of those reactions which are associated with vitality are restored the organism proceeds to work in the normal manner once more. Similarly the albumin heated in the desiccated form retains, instead of changing, that particular molecular condition which enables it, on restoring the essential conditions of moisture, to coagulate in a normal fashion when heated to a suitable degree of temperature."

During the past year it is evident that chemistry has not been entirely approached from a narrow technical standpoint, for the labours of technical research have related to problems of vitality, and to those interactions going on in the human organism the study of which is calculated to raise medicine to a higher, because less empirical, position.

PUBLIC HEALTH.

The Plague at Glasgow, and its Lessons.

The closing year of the nineteenth century will be remarkable in history from the fact that for the first time since the days of the great mortality of the seventeenth century bubonic plague obtained a footing in one of our greatest centres of industry, and the epidemiologist of the future who records the waxing and waning of pandemics will perhaps occupy himself with a comparative study of the methods of control adopted now and in the past. Perchance, too, he will have to relate that in the year 1900 Great Britain received the first indications of what was to be her share of the pandemic wave, and he may perhaps deplore that the warning was not duly heeded, in that our smaller port sanitary authorities, certain riparian authorities, and numerous inland authorities failed to appreciate the writing on the wall. It has now been sufficiently demonstrated that, however plague may behave itself in the future, we in England possess at this moment no racial immunity from it. It is important, too, that the Glasgow outbreak should be properly interpreted, and that it should not be hastily assumed that when next the disease fixes itself upon this country it will be controlled with equal success. Dr. A. K. CHALMERS—the able medical officer of health of Glasgow—has set an admirable example to the country, and we are glad to see that his successful efforts in dealing with the plague have been officially and graciously acknowledged by the Local Government Board of Scotland. We should be glad to see his services recognised in one sense in even higher quarters, and in another by the municipal authority which he has served so well. But there is some evidence to show that the plague that visited Glasgow was of a somewhat kindly type, and that the disease possessed both a low striking power *quâ* infectivity and a low fatality rate. Moreover, the evidence does not, it would seem, point to rodents, such as rats, as having actively participated in the outbreak, and in this respect the Glasgow outbreak bears a marked contrast to that which occurred in Sydney in the early part of the year. There the connexion between the disease in rats and that in man seems to have been almost demonstrated; at any rate there can be no doubt as to the association. There is one great lesson which the events of the past year have brought home to us—that is, the tendency which plague manifests to develop in the poorer quarters of a city amid surroundings where both dirt and darkness are prevalent.

The advent of plague has done much to stimulate our authorities to action during 1900, and the port sanitary survey which was undertaken by the Medical Department of the Local Government Board could not have been more opportunely timed seeing that the warnings then given were, in fact, fully justified before the survey came to a close. Until, however, the next annual report of the medical officer of the Local Government Board is published—and the interval as yet may be considerable—we are not in a position to state precisely the results of the survey. It must be patent to anyone who is at all familiar with the records of the public health service that in our smaller ports and inland districts there is an enormous amount of work to be done before anything approaching security can be even thought of. By the term "security" we do not mean to convey an idea of absolute immunity from plague. If but the foam of the next plague wave has a tendency to fleck the shores of Great Britain nothing we can do in the matter of medical inspection or of defunct quarantine will serve to keep the disease altogether at bay. The history of Glasgow alone is sufficient to demonstrate this fact, and we have recently had numerous instances—such as the case of plague at Llandaff and the several cases which occurred in the port of London—illustrative of the same conclusion. Our safety against an epidemic depends upon (*a*) the manner in which infected, or possibly infected, vessels are dealt with at our ports; (*b*) the promptitude with which the departure of passengers from such vessel to our inland districts is notified; and (*c*) the manner in which such information is dealt with. The fact that in the Glasgow outbreak plague had apparently existed for from two to three weeks before it was recognised is sufficient to indicate to us what our dangers may be, and the absence of any properly constituted port sanitary authorities in Scotland is by no means reassuring to those who fear that plague may reach us across the Scottish border. The case of Ireland, too, may have to be considered a little more in detail before we can face the future with any degree of equanimity.

In connexion with the important subject of plague mention must be made of the report issued by the Royal Commission on Plague upon the methods of preparing Mr. Haffkine's preventive prophylactic, and upon the results of its use. Although the report is on the whole highly critical, no doubt is left upon the reader's mind as to the value of this prophylactic, notwithstanding the fact that the methods of manufacture come in for somewhat severe condemnation. It is under these circumstances a matter for congratulation that there is now in this country, whether at the Local Government Board or elsewhere, a supply of this valuable material. What may be termed the serum-therapy of plague has not had the advantage of such a critical examination as has the prophylactic culture of Mr. Haffkine, and the trial of Yersin's serum at Glasgow was not such as to lead to any very definite conclusions.

The Prevention of Tuberculosis.

The year 1900 will also be noticeable by the future chronicler in another relation—although the first year of the twentieth century may have greater claims in this respect. The net cast by preventive medicine grows larger year by year, and with its increasing size the individual meshes apparently contract. It is, however, but very rarely that the net is cast around another disease, and that disease thus brought within the scope of sanitary administration. But during the past year tuberculosis has received an altogether unique attention at the hands of sanitary authorities and their officers, and the "psychological moment" has evidently arrived for vigorous efforts to be made to curtail the ravages of this disease. The congress which is to be held in London at the end of next July, and which is to be presided over by the Prince of Wales, will, it is to be hoped, have the effect of stimulating public opinion up to the passing of useful measures through the Legislature. The erection of sanatoria for phthisical patients has already received a strong impetus, and 1900 will probably be regarded as the year in which this movement had its birth in this country.

Sewage Disposal.

The Royal Commission on Sewage Disposal has continued its sittings during another year and has paid visits to certain large towns where experimental works are in progress. We should be glad if we were able to anticipate the issue of at least an interim report which would have the effect of defining the position of the Commission relative to the important and really pressing subject as to whether or not the use of land is still to be insisted upon in all systems of sewage disposal, but we fear the knowledge hitherto acquired is not yet such as is capable of being focussed.

Food Preservatives and Substitutes.

The important question of the use of certain chemical preservatives in our food and drink has continued during the year to receive the attention of the Departmental Committee of the Local Government Board, and visits have been paid by members of that committee to Holland, Germany, Denmark, and Ireland, with a view to ascertain the practices in vogue in these countries in respect of this matter. Whatever may be the decision at which the committee arrives, some valuable evidence and important experimental results will doubtless be placed on record. Probably, too, the medical profession will in future pay more attention to this subject than has hitherto been the case. The uncontrolled use of substances which are at one and the same time both drugs and preservatives can hardly fail at times to lead to posological complications, seeing that the medical practitioner who prescribes one of the drugs in question may be quite unaware that his patient is already being, and has perhaps for years been, over-dosed with the same substance.

That there is pressing need for a more detailed examination of our food and drinks, and of the substances used in their preparation, has been recently brought home to us in a somewhat dramatic and startling fashion by the revelations as to the presence of arsenic in beer, and a question asked lately in Parliament as to the number of samples of sulphuric acid which have been examined by the Government analyst during the past year seems to indicate the direction in which reform is most urgently called for. In the matter of beer, as in certain other directions, the responsibility *quâ* purity is, it appears to us, not sufficiently defined, and the fact that the Treasury, the Home Office, the Local Government Board, the Board of Agriculture, and the Inland Revenue have certain functions and interests in this matter, has led to less control being exercised than obviously should have been the case.

The Prevention of Malaria, Yellow Fever, and Typhoid Fever.

In the domain of tropical medicine great advances have been made in our knowledge of the prevention of malaria by the destruction of certain species of mosquitoes, and the practical experiments conducted in the Roman Campagna and on the west coast of Africa have gone far to show that if the bites of these mosquitoes can be prevented, so also can malaria; in other words, that if the formula, "No mosquitoes, no malaria," does not convey all the truth, it does so to such a degree as to render action in this direction the most practical measure for controlling the disease. Dr. Celli and Dr. Koch have also laid much stress upon the presence of rice-fields as conducing to malaria, and the latter has remarked, "The more rice fields there are in the neighbourhood of a place, and the nearer they are, the greater the abundance of mosquitoes."

The terrible prevalence of enteric fever among our troops in South Africa has afforded an altogether exceptional opportunity for the study of this disease under the conditions of modern warfare, but it is deeply to be regretted by all true epidemiologists that more advantage was not taken of the situation by the despatch of a really capable committee of trained epidemiologists to investigate the situation at the actual moment of prevalence. Doubtless the Commission which was despatched a few months since will bring back much highly valuable information, but it is quite clear that they have not been afforded a fair opportunity for adequate research. Some 15,655 cases, 3642 deaths, and 9128 invalids, will require no little investigation. Anti-typhoid inoculation has been submitted to some experimental tests in South Africa during the year under review, but we must await the official returns before judging the results.

The etiology of yellow fever has been further cleared up during the past year by Dr. **WASDIN** and Dr. **GEDDINGS** of the Marine Hospitals Service, Washington, U.S.A., who, in their report issued at the beginning of 1900, confirmed in most of the essential details the discoveries of Professor **SANARELLI** with reference to the bacillus icteroides being the specific organism of that disease and have also demonstrated that the infection of the disease is taken in by the breath.

The Housing of the Poor.

In the more exclusively administrative side of public health the year 1900 will for some five millions of our population situated in the County of London mark a new departure, and upon the corporations which have now replaced the old vestries will devolve the duty of guarding the health of the new metropolitan boroughs. All students of local government will watch the new corporations somewhat critically and anxiously to see if they set an example of purity of life to the local authorities throughout the country, or whether they degenerate into aggregations of interested place seekers unduly influenced by the jerry-builder and insanitary property-owner. In connexion, however, with the subject of slum property the year 1900 has seen some good work, and although the modified machinery for applying the Housing of the Working Classes Acts cannot be accepted as in any sense final Mr. **CHAPLIN'S** Act may prove helpful to local authorities. The London County Council, too, are taking steps which may afford some useful lessons to those who are endeavouring to face these problems seriously, and the improved means of transit afforded by electric tramcars and underground railways must be regarded as not unconnected with the problems of the housing question.

Vaccination.

The new Vaccination Act, on the whole, is working smoothly, although in more than one large town the anti-vaccinationist is in a more fighting mood than are the officers whose duty it is to enforce the Act. But there seems little room for grievance left, and the scenes which took place under the old Act have ceased to occur. Still, Mr. **WALTER LONG**, the new President of the Local Government Board, must exert considerable tact and firmness if he wishes to report to Parliament at the expiration of the period for which the Act is operative that unqualified success has attended its administration. But the fact that the percentage of vaccinations to births was in 1899 72·1, as contrasted with 54·2 in 1898—an increase of 33·8 per cent.—is decidedly hopeful. Moreover, Mr. **LONG** has already shown himself to be a Minister of remarkable determination, and, if we mistake not, he will prove a vigorous administrator.

The Disposal of the Dead.

The sanitary condition and resources of London burial-grounds have been inquired into by the medical department of the London County Council during the past year and some interesting information has been accumulated. The indications are that the old idea of preserving the dead must give place to one which will expedite the resolution of our remains rapidly and withal inoffensively—that leaden coffins and deep brick graves must find a substitute in a method which will be more in keeping with the "earth to earth" of our burial service, with the findings of the bacteriologist, and with the dictates of economy; while for those who view with distaste even this relatively rapid decomposition of the body by earth-to-earth burial there is an increasing number of crematoria being erected where the same final result can be reached in the course of some two hours. The number of persons who appreciate this somewhat sudden rupture of material associations increases year by year, and it is estimated that at Woking alone at least 300 bodies have been thus dealt with during 1900. How will these figures compare with those for the year 2000?

Sanitation in Dublin.

The persistence of an exceptionally high death-rate in Dublin was in part explained by the description which our Special Sanitary Commissioner gave of the insanitary conditions prevailing there at the commencement of the year. As children had been the principal sufferers the reports which we published dealt extensively with the elementary schools. Many of these are situated in extremely unhealthy and overcrowded districts. They have not sufficient playgrounds or breathing space around them, but are wedged in between filthy dwellings or abut upon lanes where offal and offensive matter are allowed to accumulate. Inside the light is often deficient and sometimes no provision, or only very scant and insufficient provision, is made for washing. The children, especially at the industrial schools, are often extremely dirty, and it is not to be expected that under such circumstances they will grow up to appreciate the advantage of cleanly habits and healthy homes. These homes are generally in old houses that were built for one family but which have now been turned into tenements where many families reside. Of course they are not suited for such a purpose and the property is soon degraded. Filth of the most revolting description abounds on all sides, yet many of these slum dwellings are in the very centre of the town and near to the most fashionable quarters. There have been some noble efforts made to deal with the question of the housing of the poor, but in face of widespread poverty, of the dirty habits of the people, and of their complete ignorance of the principles of cleanliness these endeavours have only touched the fringe of the problem. Consequently epidemics follow one upon the other with regrettable and monotonous regularity. Much might be done to mitigate these evils if object lessons and practical lessons were given in the schools in cleanliness and domestic economy. Unfortunately, political and religious animosities hold the first rank where only practical questions of local administration should be dealt with, and in the wrangle of party strife the cause of sanitary reform is thrust into the background. Even in the management of hospitals the same strife occurs and sisterhoods interfere on religious grounds with purely technical medical matters. This introduction of religion and politics as dominating factors over matters of technical administration is one of the greatest obstacles in the way of efficient sanitary reform, and yet it is only necessary to refer to the appalling description given in our columns of the condition of Dublin to appreciate how much such reform is needed.

THE GENERAL MEDICAL COUNCIL.

The sessions of the General Medical Council have been of considerable interest from the number of important questions which have been raised as well as from the nature of the cases brought under the disciplinary notice of the Council. Important changes in the *personnel* of the Council have to be recorded as affecting the character of its debates. Mr. **R. BRUDENELL CARTER**, who long and ably represented the Apothecaries' Society of London, has been replaced by Sir **HUGH REEVE BEEVOR**. Sir **RICHARD THORNE'S** death was much felt in the Council. He was not restrained by his official position or by temperament from sharing boldly in the fray of discussion on all subjects. The great interests of the Crown in State Medicine are happily well guarded by his successor, Mr. **W. H. POWER**. If he has not yet acquired that freedom of debate which characterised his predecessor all who know him recognise that the Council has gained in him a clear and logical head. Sir **PHILIP C. SMYLY** resigned before the November meeting, and was succeeded in the representation of the Royal College of Surgeons in Ireland by Dr. **CHARLES BENT BALL**.

Professor ALFRED HARRY YOUNG takes the place of the lamented Dr. D. J. LEECH as representative of the Victoria University. A new member, adding to the size of the Council by representing a new constituency—Birmingham University—is Professor BERTRAM COGHILL ALAN WINDLE. Mr. WINTERBOTHAM has been appointed solicitor to the Council, on the resignation, after long and valued services, of Mr. F. W. FARRER. A well-deserved vote of thanks to Mr. FARRER was passed.

At the May meeting of the Council the deliberations were prolonged through nine days. Three days were almost wholly given up to the penal cases. One of the practitioners, a dentist, whose name was ordered to be erased was charged with "systematically seeking to attract professional practice by the issue of public advertisements of his name, address, appliances, and professional qualifications." This should serve as a warning to dentists, many of whom have a tendency to advertise in a way quite inconsistent with the status now conferred upon them by Act of Parliament. Such conduct will in future be the less excusable, because at this session the Council ordered its resolution disapproving of advertisement to be issued to every dentist on the Register.

At the November session there were, amongst others, two penal cases, involving somewhat new forms of complaint, which call for a short notice here. One was that of HENRY WARD IRVINE of Birmingham, registered as M.B., Bac. Surg., M.D., Univ. Dub., who had accepted office in an institution called the Consultative Medical and Surgical Institution, Birmingham. By the promoters of this institution he was extensively advertised as its consulting physician, and the question was whether he had condoned such advertisement and must therefore be considered to have advertised. The Council found the charge against Dr. IRVINE of infamous conduct in a professional respect proved and adjourned the further consideration of the case to the next May session. The other case was that of JOHN MARTIN THOMSON, of Airdrie, N.B., registered as M.B., Mast. Surg., Univ. Edin. He was charged with keeping a chemist's shop and employing assistants for the sale of drugs and poisons who were not qualified to act as chemists or pharmaceutical assistants. The chief defence was that the custom was universal in that part of Scotland. The Council found the charge proved and adjourned the further consideration of the case to the next May session. The prevalence of such a custom throughout Scotland is a matter of some importance to the Council, who should ask for proof of this statement with a view to formulating procedure. The construction of rules to prevent fraudulent personation seems to be attended with some difficulty, as the report of the committee in May was recommitted, and even in November no final report was presented.

The financial position of the Council is interesting. At the May meeting the Council gave, as a part of its expenses, £500 to the Branch Council of Ireland, which finds increasing difficulty in carrying on its branch work with the funds accruing from its own registrations. The other Branch Councils are in a better financial position, but, as may be seen from the report of the Special Finance Committee made at the November session, there is a tendency in late years for the expenditure to exceed the income. This is not so much from a falling off in income as from ever-increasing expenditure on law proceedings, on long sittings of the Council, on stationery, and generally by that lavish and generous humour which is generated in a body which has for some years accumulated money without using it. It will be seen that there is considerable difference of opinion in the Council as to the exact financial situation, some members being disposed to regard it more favourably than others. It is satisfactory that the Council has resolved that the whole financial position is to be referred to an expert for his consideration and advice and that his report is to be in the hands of members of the Council a month before the next meeting. There should be no serious difficulty in adjusting the income and expenditure of the Council, for the property of the Council is rising in value and the annual deficit is not a serious one.

A more difficult question than the financial one is the adjustment of the relations between the General Medical Council and the medical authorities, and the definition of their respective functions. Anything more unseemly or unprofitable than the friction between the Royal Colleges of Physicians of London and Surgeons of England on the one hand and the General Medical Council on the other, in respect of the recognition of institutions for the teaching of chemistry, physics, and biology cannot be imagined, and unfortunately it is only emphasised by the resolution of the Council at its late meeting to "adhere" to a position which it has no legal power to sustain and which may easily involve it in costly and undignified litigation. The calm judgment of the President will, it is to be hoped, avail to moderate feeling on both sides.

At the May meeting valuable reports from the experts who had been consulted by the Council as to the best means of raising the standard of preliminary education were presented by the Education Committee. The Council adopted the view of the committee that while it was not possible in the existing condition of education to require from all intending medical and dental students the standard of general attainments represented by the so-called senior and higher grade examinations, a substantial advance can be made by insisting on improvements in the character and stringency of junior examinations. Especially can these examinations be influenced by the Council who can require that candidates shall have obtained a higher standard than that of a simple pass. It was also determined to refuse registration to all students who have not attained the age of 16 years. At the November meeting it was reported that all the educational bodies were endeavouring to comply with the views of the Council.

An ill advised suggestion of the Public Health Committee to divide candidates for Public Health Diplomas into two classes, junior and senior, and to facilitate unduly the acquisition of such diplomas by colonial practitioners was not accepted by the Council, which is sensible of its responsibility in this matter and of its power to enforce its views. At the November meeting the subject was disposed of by making the demands equal from all classes of candidates as respects the time to be devoted to laboratory work and work under a medical officer of health.

An important reminder of the subjection of the General Medical Council to the Privy Council in some subjects was supplied in May by an intimation from the latter body that at the proper time it will be prepared to apply Part 2 of the Medical Act, 1886, to Italy. This means, of course, that in due time some recognition of the rights of Italian medical practitioners to practise in England and *vice versâ* may be arranged. After the Order in Council the part of the General Medical Council under the Act comes into play in deciding before conceding registration whether any given foreign diploma guarantees sufficient knowledge and skill, and whether the applicant is of good character. It rests with the Queen in Council to decide if Italy has accorded just conditions of practice to Her Majesty's medical subjects in that country. The information conveyed in our Rome correspondent's letter last week, however, would indicate that it is very doubtful whether Her Majesty in Council will be in a position to declare that her medical subjects in Italy have been accorded "just conditions of practice."

THE BRITISH MEDICAL ASSOCIATION.

The sixty-eighth meeting of the British Medical Association was opened at Ipswich on Tuesday, July 31st, under the presidency of Dr. WILLIAM ALFRED ELLISTON, senior surgeon to the East Suffolk and Ipswich Hospital. This is the first occasion upon which the Association has met at Ipswich. The meeting of the Association was this year rather handicapped by other meetings which occurred about the same time, notably the Centenary of the Royal College of Surgeons of England and the International Medical Congress held at Paris. But, on the whole, the meeting was successful and saw the beginning of a reform movement that may later be found full of significance. The Presidential and other addresses were, as might have been expected in the last year of a century, retrospective. Dr. W. A. **Elliston** took for the subject of his address Some Incidents in the Evolution of the Modern Physician Mr. F. **Treves**, who gave the Address in Surgery, spoke upon the Surgeon in the Nineteenth Century. Dr. W. J. **Smyly**, who gave the Address in Obstetrics upon the Maternal Mortality in Childbed, took a retrospect of the subject as it appeared from the beginning of the century until now; and only Dr. P. H. **Pye-Smith**, who gave the Address in Medicine entitled "Medicine as a Science and Medicine as an Art," resisted the temptation to sum up the progress and the mistakes of the century. The discussions and papers were all round maintained at a high level, although there was nothing very startling to the fore. But the Ipswich meeting of 1900 may become memorable in the annals of the Association by reason of the carrying of a motion proposed by Mr. **Victor Horsley** in the following terms:—

> "That a committee be appointed to consider and report upon the best means of reorganising the constitution of the British Medical Association, such committee to furnish a provisional report to the branches by March 1st, 1901."

After the date had been altered from March 1st to Feb. 1st this motion, which was unanimously carried on August 1st, resulted in the appointment of the following gentlemen as a committee. Those nominated by the Council were as follows:—For South Africa, Surgeon-General J. B. **Hamilton**; for the East Indies, Mr. **James Cantlie**; for Ireland, Sir **John Moore**; for Scotland, Dr. J. C. **McVail**; and for England, Dr. **Roberts Thomson**, Dr. **Radcliffe Crocker**, Mr. T. **Jenner Verrall**, Dr. R. **Saundby**, Dr. S. **Woodcock**, Dr. **Ward Cousins**, Mr. H. T. **Butlin**, and Mr. **Andrew Clark**. Mr. **Horsley's** nominations were: for the West Indies, Dr. C. G. **Gooding**, late of the Barbadoes; for Australasia, Mr. C. G. D. **Morier** of Adelaide; for Scotland, Dr. R. C. **Buist** of Dundee; for Ireland, Professor J. W. **Byers**; for Canada, Mr. **Edmund Owen**; for England, Dr. A. **Cox**, Dr. **William Gordon**, Dr. C. H. **Milburn**, Dr. A. G. **Bateman**, Dr. A. B. **Ritchie**, Mr. J. S. **Whitaker**, and Mr. **Victor Horsley**. The report of the committee should be of great interest to the Association, that is, to a large section of the British medical profession.

VARIOUS HOSPITAL FUNDS.

When the many calls upon the purses of the charitable during the past year are taken into consideration the promoters of the Metropolitan Hospital Sunday Fund are to be congratulated upon the success of their labours on behalf of the sick and needy poor of the Metropolis. Under the presidency of the Right Hon. Sir **Alfred J. Newton**, Bart., Lord Mayor, treasurer of the Fund, a total of £51,993 14*s.* 6*d.* was collected. This shows a falling off from last year when the total was £53,504 11*s.* 1*d.*, but not including last year the present total is the largest one since 1895. The amount collected by the various congregations was £35,856 8*s.* 11*d.* and the legacies, special donations, &c., made up a sum of £16,137 5*s.* 7*d.*, this latter sum including £10,000 from Mr. **George Herring**, £1090 from the late Mr. **Thomas King** of Tisbury, Wilts, and an anonymous donation from "F. H." of £1000. It should be mentioned that Mr. **Herring** offered to give an additional £10,000 if the collection could be raised to £90,000. Sir **Savile Crossley** for the tenth time gave £500; "A. G. P.," £300; and "Delta," for the twenty-second time, £200. At the meeting of the committee of distribution in July it was decided to divide the sum of £46,492 among 140 hospitals and 54 dispensaries. Among the largest of the contributions from the congregations the Rev. Prebendary C. J. **Ridgeway**, of Christ Church, Lancaster-gate, headed the list of contributions with £1519, and the Rev. Canon **Fleming** of St. Michael's, Chester-square, collected £1158 from his congregation. The Rev. Prebendary **Eardley Wilmot**, M.A., of St. Jude's, South Kensington, collected £855.

The energy displayed by the workers for the Hospital Saturday Fund is worthy of all praise. Notwithstanding the exceptional strain upon public charity this year this Fund shows no falling off; indeed, up to the end of last week it was £184 ahead of the amount collected up to the corresponding period last year. The accounts of this Fund are not made up until the new year, so that no proper comparison can be drawn between this and the other metropolitan funds. The amount distributed last year was £17,013 13*s.* 8*d.*, a sum practically made up of the pennies of working-people. An interesting fact worthy of note in connexion with this Fund is that the deficit which was at first entailed by the abandonment of the annual street collection has in three years been fully made up.

The Prince of Wales's Hospital Fund has this year received £26,888 in annual subscriptions, £8523 from donations, undefined contributions, and newspaper collections, £6038 from investments, £1000 from a legacy by Madame **Rosa Ann Deleglise**, £1000 as an annual grant from the trustees of the London Parochial Charities for the maintenance of convalescent hospitals, and other smaller sums, making a total of £43 468 13*s.* 1*d.* In addition to this £6000 were received from the League of Mercy. The annual subscriptions show an increase of £1200 over the amount of last year. The donations, on the other hand, are £5000 less. A legacy of £3000 from Sir H. P. **Turner Barron** will probably be paid in 1901. £50,000 have been distributed, of which £49 000 went to hospitals and £1000 to convalescent homes. This is an increase of £8000 on the amount distributed last year, and last year there was an increase of £9000 over the previous year.

In application to all the funds we heartily re echo the words of His Royal Highness the **Prince of Wales** when recently in referring to his own Fund he said: "I can only hope that as time goes on the Fund may increase in prosperity, so that the great object we had in view, that of placing the hospitals of this great metropolis on a thoroughly sound financial basis, may be accomplished."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The manner in which Dr. **William Selby Church** fulfilled the duties of President during his first year of office left but little doubt as to his re-election, and at a comitia held on April 9th Dr. **Church** was again installed in the chair by an almost unanimous vote of the Fellows. On July 11th the President informed the College that he had accepted the invitation made to him, as President of the College, by the Secretary of State for the War Department, to become a member of the Commission appointed by the Government to inquire into the condition of the sick and wounded in South Africa, and in accordance with the by-laws he nominated Dr. F. W. **Pavy** to act as President during his absence.

During the year an important alteration was made in the by-law dealing with the permanent or temporary expulsion of a Fellow, Member, or Licentiate from the College.

A report, dated Nov. 20th, from the Committee on the Nomenclature of Diarrhœa was received, in which it was recommended that the term "epidemic enteritis" should be used as a synonym for epidemic diarrhœa and that the College should urge the entire disuse as synonyms of epidemic diarrhœa in medical certificates of death of such terms as "gastro-enteritis," "muco-enteritis," or "gastric catarrh."

By laws were enacted and approved relating to the representatives of the Royal College of Physicians of London who should be appointed members of the University of London. It was determined that the representatives should always be Fellows of the College and the mode of their election was precisely laid down.

The subject of the Weber-Parkes Prize Essay for 1903 was announced to be "The Channels of Infection in Tuberculosis, together with the conditions, original or acquired, which render the different tissues vulnerable"

A communication was received from the Secretary of State for the War Department asking the advice of the College on a proposal for encouraging the investigation of the nature and cause of dysentery affecting armies in the field and its relationship (if any) to enteric fever. The President was requested to express to the Secretary of State the hearty appreciation of the College of the proposal submitted and to suggest that in its opinion the end in view would best be attained by appointing a small commission of suitably qualified persons to conduct the inquiry. A subsequent communication from the Secretary of State announced the appointment of the following commissioners:—Dr. W. J. R. SIMPSON, Colonel J. L. NOTTER, R A.M.C. (Professor of Military Hygiene, Army Medical School, Netley), and Major D. BRUCE, R.A.M.C.

The following awards were made during the year:—The Blane Medals to Staff-Surgeon JAMES M. ROGERS, R N., F.R.C S. Eng., and Surgeon OSWALD REES, R.N., M.D Glasg., and the Jenks Scholarship to Mr. ALFRED GEORGE SWAN.

The following lectures were delivered during the year: the Milroy Lectures by Dr. F. J. WALDO on Summer Diarrhœa, with Special Relation to Causation and Prevention; the Goulstonian Lectures by Dr. PERCIVAL HORTON-SMITH on the Typhoid Bacillus and Typhoid Fever; the Lumleian Lectures by Dr. W. B. CHEADLE on Some Cirrhoses of the Liver; the Croonian Lectures by Dr. F. W. MOTT on the Degeneration of the Neurone; and the Bradshaw Lecture by Dr. ARCHIBALD E. GARROD on the Urinary Pigments in their Pathological Aspects. Professor CLIFFORD ALLBUTT was the Harveian orator for the year.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The chief event of the year 1900 has certainly been the celebration of the centenary of the granting of the Charter in 1800, whereby the old Surgeons' Company, which had become dissolved, was reconstituted and incorporated under the name of the Royal College of Surgeons of England. About a year ago the Council obtained a Supplementary Charter whereby they became empowered to grant diplomas of Honorary Fellowship not exceeding 50 in number. The centenary celebrations commenced with the conferring of the Honorary Fellowship on the PRINCE of WALES. A conversazione took place at the College and the centenary meeting was held in the late theatre of the University of London, when the President, Sir WILLIAM MACCORMAC, welcomed the guests, and then conferred the honorary diplomas on 34 foreign and British representative surgeons. It should be mentioned, however, that in addition to the PRINCE of WALES the Marquis of SALISBURY and the Earl of ROSEBERY were also made Honorary Fellows. On the same evening was held the centenary dinner in Lincoln's Inn Hall The centenary festival was in every way a success and was worthy of the College and of the occasion.

At the annual election of members of the Council there were four vacancies, as Sir THOMAS SMITH, Mr. JOHN TWEEDY, and Mr. ALFRED COOPER retired, and Mr. J. N C. DAVIES COLLEY had resigned and subsequently died. Sir THOMAS SMITH did not seek re-election, but there were in all 12 candidates, and Mr. TWEEDY and Mr. COOPER were re elected and Mr. A. PEARCE GOULD and Dr. J. WARD COUSINS were elected.

The annual meeting of Fellows was fixed for July 5th, but the number required for a quorum not being present no meeting was held. This is the fourth time that a meeting has been summoned and a quorum has not been present, and it is not at all unlikely that in future the regular meetings will be discontinued and that a meeting will only be summoned when the Council considers it necessary.

The annual meeting of Fellows and Members was held on Nov. 15th, when the Council was requested to have the names of deceased Members printed in the annual report, and a resolution was carried to the effect that the Council was asked to obtain representation for the Members. Another resolution requested the Council to take steps towards obtaining a Parliamentary inquiry into the working of the Medical Acts with a view to their amendment. A further resolution expressed the opinion that every Member of the College was entitled to receive a copy of the annual report from the Council without application. Another resolution asked the Council to agree to the recent recommendations of the General Medical Council with regard to the combination with the Apothecaries' Society and the question of the commencement of scientific studies. The Council at its next meeting acceded to the request that the names of the deceased Members should be published in the annual report, but they thought that it was not desirable to re-open the question of the representation of the Members on the Council It was also decided that the annual report should be sent to those Fellows and Members only who apply for it.

Two Members were elected to the Fellowship under the 20-years' rule—Brigade-Surgeon-Lieutenant Colonel W. R. HOOPER, C.S I, I.M.S., and Mr. FREDERICK PAGE of Newcastle. Mr JOHN LANGTON delivered the Bradshaw Lecture on the Association of Inguinal Hernia with the Descent of the Testis. The Jacksonian Prize was awarded to Dr. LAMBERT LACK for an essay on the Pathology, Diagnosis, and Treatment of Inflammatory Affections of the Nasal Fossæ and the Associated Sinuses and Air Cells. The subject of the Jacksonian Prize for 1901 is the Diagnosis and Treatment of Bullet-wounds of the Chest and Abdomen. The John Tomes Prize was awarded to Mr. J. H. MUMMERY. Mr. EDWARD TRIMMER, M.A, the Secretary of the College, who has been connected with the institution for 42 years, has resigned, and his resignation will date from March next. Mr. SIDNEY COWELL, B.A., who has been assistant secretary, has been appointed to succeed him.

BENEVOLENT AGENCIES OF THE PROFESSION.

The Royal Medical Benevolent College, which provides pensions for aged medical men and the widows of medical men in reduced circumstances and a school open to all classes but offering special advantages to the sons of medical men, 50 of whom are foundation scholars, sorely needs greater support than it receives. There are 50 pensioners, all of whom receive annuities of £30, with the exception of a few still occupying rooms in the asylum who receive £21. There are also nine "Pugh" pensioners who receive £30 a year each, two "Da Silva" pensioners, each of whom receives a pension of £20 per annum in addition to the out-pension given by the College, and three "Morgan" annuitants who receive annuities of £20 each. 50 foundation scholars receive an education of the highest class and are boarded, clothed, and maintained at the expense of the College. Nine perpetual presentations for female orphans of medical men and one with certain restrictions open to those who are not orphans exist in connexion with the College at the School of St. Anne's Society. As the College has not much in the way of permanent income the cost of maintaining the 50 foundation scholars and the 50 pensioners has to be defrayed mainly out of the annual subscriptions and donations and these have for some years past been insufficient for the purpose.

The income of the British Medical Benevolent Fund has barely covered the outlay and subscriptions are urgently needed to maintain the efficiency of the grant department. The annuity department shows an income from investments of £2350, while the amount paid in annuities is £2213. The annuitants number 111. In the grant department the income from subscriptions and donations is £1691, while the amount voted by the committee in payment of grants totals £1685. Had it not been for two large and unexpected donations there would have been a serious deficiency. 165 cases have been relieved.

The Society for the Relief of Widows and Orphans of Medical Men was founded in 1788 and incorporated by Royal Charter in 1864. The benefits of the society are confined to the widows and orphans of deceased members of the society, and any registered member of the profession residing within a radius of 20 miles from Charing Cross is eligible for proposal as a member of the society. The receipts for 1899 amounted to £3353 and the grants and expenses to £3250 13*s.* 1*d.*

THE LANCET Relief Fund still continues to relieve cases of temporary distress, and the report for 1900, which will be published in an early issue of THE LANCET, will probably show that the number of cases dealt with this year is greater than that of last year. The amount expended in gifts may also show an increase.

ANALYTICAL COMMISSIONS OF THE LANCET.

The investigations undertaken in THE LANCET Laboratory during the past year have been of general interest. In view of the inquiry into the question of the use of preservatives and colouring matters in food by a committee appointed by the Local Government Board—before which committee one of our Commissioners gave evidence—it occurred to us that a history of the subject would be looked for at this stage and only in the past pages of THE LANCET could such a history be found. In 1851 public attention was first drawn to the preservation and artificial colouring of food by the labours of the Analytical Sanitary Commission of THE LANCET instituted by the late Mr. THOMAS WAKLEY, M.P., the Founder of the journal. In the first number of the present year will be found an article entitled "An Historical Record of the Use of Preservatives and Colouring Matters in Food, according to the Inquiries of the Analytical Sanitary Commission of THE LANCET from 1851 to the present time." This article is a *résumé* of the various articles and communications which appeared in THE LANCET when the subject was first mooted half a century ago, and we believe that this historical synopsis has proved instructive in showing the origin and early uses of artificial colouring matters and preservatives in food, as well as by drawing a contrast between past and present methods. The committee of inquiry referred to has not yet reported or drawn up any recommendations as to the direction in which legislation may be directed for the better security of a pure food-supply from the points of view indicated. We predicted that the inquiry would involve a considerable amount of time and labour, though we believe the Local Government Board at the outset thought that short work could be made of the subject in hand. As it is the inquiry has lasted well over a year and the report is not yet to hand, but a question recently put in the House of Commons elicited the statement that it might be ready by March next.

In THE LANCET of May 5th (p. 1298) our Commissioners drew attention to the composition of custard powders which are so often recommended in place of eggs for the preparation of a custard. As a matter of fact our analyses of several powders showed that the albumen found in them ranged from 3 per cent. to *nil.*, while in none of them was there any fat. They consisted chiefly of starch coloured with turmeric or an aniline dye. As was pointed out, such a mixture cannot compare dietetically with the true custard made with milk and eggs. The matter is of some importance, especially as custard is employed as an acceptable food for invalids. The custard powders examined were in no sense equal to eggs and milk.

In the same number of THE LANCET (p. 1299) appeared a chemical account of the colouring of the new halfpenny postage stamp which early in the year was altered to green from red in order that it might conform with the colour of the stamps of the same value in other countries. The colouring we found to consist of a mixture of Prussian blue and a chrome colour. No lead or arsenic, or other mineral irritant could be found. The gum was the dextrinous substance derived by heating starch, called British gum. The chemistry of the new halfpenny stamp, therefore, is satisfactory, but, of course, as our readers were reminded, postage stamps are constantly exposed to the risk of contamination with septic organisms, which fact renders the common habit of licking them very undesirable.

Statements appeared frequently in the press in the early part of the year to the effect that amongst other unfair devices adopted by the Boers in the present war was that of coating the Mauser bullet with a poisonous salt of copper. By the courtesy of Sir WILLIAM MAC CORMAC, who placed at our disposal some of the so-called copper-dipped bullets, our Commissioners were able to submit the coating, as well as the case which enclosed the bullet, to analysis. The metal case was found to contain both nickel and copper. The wax outside was shown to be identical with that used in candle-making. Since candle-wax contains stearic acid it would most likely act upon the metal of the case, producing in a similar way the green "tears" commonly found hanging from brass candlesticks. A good deal of the wax could be scraped off and was quite white, the green portion being next to the metal case. In this layer of wax both nickel and copper were found. These results were quite inconsistent with the theory that the Boers had maliciously coated their bullets with poisonous copper salts.

The next subject which engaged the attention of our Laboratory Commissioners was the Sparklet system of extemporaneously aerating liquids. The inquiry related to (1) the safety of the method arising from (*a*) the sparklet or bomb containing liquid carbonic acid gas and (*b*) from pressure in the charging bottle; (2) the purity of the gas; and (3) the purity of the finished product and its chances of contamination. We were satisfied as to the safety of the method and to a great extent also as to the purity of the aerated liquid obtained. On this last point, however, we made a few suggestions which if acted upon should give greater security in this regard.

A very interesting enterprise in the direction of hydrotherapeutics at Shanklin in the Isle of Wight was the next subject of inquiry. We refer to the ferruginous baths which have recently been constructed there on the exact plan adopted at Homburg Spa, Schwalbach, and elsewhere. A number of analyses of the water of the ferruginous spring at Shanklin Spa were made on the spot, and afterwards a complete account of the composition of the water was published from THE LANCET Laboratory. At the same time the ingenious system of heating the baths, by means of which the natural condition of the water is undisturbed, was described with some detail.

The number of specimens of food, drugs, and other articles examined in THE LANCET Laboratory and reported on in our Analytical Records column was exactly 100, and the number of individual determinations thus involved was 373. In connexion with special analytical work some 34 analytical determinations were made, bringing up the total analyses to 407.

THE INTERNATIONAL CONGRESSES IN PARIS.

Early in 1899 we began the publication of articles designed to arouse interest in the great international medical congresses to be held in the following year in connexion with the Universal Exhibition at Paris. It must be confessed that our endeavours did not meet with that measure of success which, under normal circumstances, would have been secured. As we have always maintained that the progress of science should not be checked by frontier demarcations, we have been anxious that Great Britain should be adequately represented at all international scientific gatherings. This year the war in South Africa very materially interfered with our aspirations in this respect. So many physicians and surgeons went to the front that those who remained in England had more than their usual amount of work to do and were therefore less able to find time to attend congresses. Also, the natural anxiety caused by the war and the mourning for lost friends or relatives made others less inclined to take part in congresses and their accompanying festivities. Thus the medical world at the Paris Exhibition had to endure the absence of many who, under more propitious circumstances, would have largely contributed to uphold the fame of British science in these parliaments of the world. So also with regard to the Exhibition itself, we fear that its innumerable useful and practical lessons have been lost to many members of the profession who in normal times would certainly have visited this unparalleled collection of the works of civilisation. At any rate we have endeavoured to supply our readers with descriptions of the Exhibition and of the many congresses.

First International Congress on Deontology.

Particularly anxious were we to give the fullest prominence to all that was done to improve the moral and material position of members of the medical profession. The economic evolution which is revolutionising the social conditions of all the great industrial peoples has also affected the medical profession, and not only in Great Britain, but throughout all civilised countries. Consequently, we have had, for the first time in European history, a great international congress attended by medical men from all parts of the world, gathered together to discuss solely the economic position of medical practitioners, and the ethical principles necessary to meet and to mitigate newly developed evils. Unfortunately the attendance of British representatives was very small, and this was due, not only to the causes enumerated above, but also to the fact that the International Congress on Medical Deontology or Ethics met at about the same time as the annual meeting of the British Medical Association. Nevertheless, the economic difficulties that beset the medical profession in England were explained to the congress, amongst others by our Special Commissioner, who has now for several years been contributing special reports on the subject to these columns. From Germany and Austria came encouraging accounts of the formation in those countries of medical chambers somewhat after the model of chambers of commerce. Medical associations in Hungary, Roumania, and Norway also give good promise, while the medical syndical chambers or unions of France and Belgium are militant institutions that are really fighting very actively for necessary reforms. All this work of organisation has also influenced the legislature of some countries and the laws regulating medical practice have been improved. The results altogether of this first congress were so encouraging that it was determined to continue the work, and a second International Congress of Deontology will be held in Belgium three years hence. It is to be hoped that on that occasion Great Britain will be better represented than she was at the first congress.

First International Congress of the Medical Press.

But this was not the only congress dealing with the organisation of the medical profession. It was followed immediately by the International Congress of the Medical Press, at which THE LANCET, the *British Medical Journal*, and a great number of continental and American medical journals were represented. In some countries the necessity for an improvement in the medical press is, unfortunately, but too evident, and this congress was the first step taken in that direction. The object was to convert medical journalism into a profession actuated by a proper sense of its dignity and governed by self-imposed and generally recognised ethical laws. In this wholesome work the British medical journalists were able to take a leading part. But a great difficulty arose in defining what really constituted a medical journalist. Should a medical man engaged in medical practice own and edit a medical journal? If so, what was to prevent such a paper becoming a means of self-advertisement? Again, if the journal, as is the case with regard to some journals on the continent, is owned by a firm of wholesale druggists, what was to prevent such a journal from becoming a means of unfairly advertising the special drugs produced by that particular firm? How to create in all countries a medical press that should be above suspicion and to secure the services of medical journalists who should be sufficiently paid to be fearless and independent in their criticisms is a problem hard to decide in countries where many of the so called medical journals are little better than trade circulars. That this ideal had actually been achieved in England was a source of much encouragement to the congress; and in this congress, at least, the British representatives were able to occupy the foremost rank and to render efficient help to the work taken in hand. So complex were the difficulties, so urgent was the need of reform, that the congress not only resolved to meet again, but instead of deferring such meeting for some years it was decided that the Second International Congress of the Medical Press should be held at Brussels next year.

Thirteenth International Congress of Medicine.

Hardly had this congress terminated than the largest of all the congresses began, for more than 5000 delegates and members attended the Thirteenth International Congress of Medicine. Divided into 28 sections, each section constituted a congress in itself and each will issue a weighty volume describing its proceedings. The papers read in these sections bore evidence of a great deal of hard work, but the new theories broached or new discoveries described were not numerous. Apart from the ordinary debates many visits were made to various hospitals and cliniques, and of course to the technical sections of the exhibition. On the other hand, some of the State receptions and entertainments that had been announced were postponed in consequence of the assassination of the King of ITALY, which occurred just before the congress met. A large staff of able collaborators enabled us to give our readers a very full account of the International Medical Congress.

Tenth International Congress of Hygiene.

The Tenth International Congress of Hygiene and Demography followed upon the International Medical Congress, and of all the four great medical congresses it was certainly the best organised. The Congress of Deontology was also well managed, while that of the Medical Press, being necessarily small, did not give rise to any great difficulty in regard to management, but there was certainly a good deal of blundering over the International Medical Congress. The Congress of Hygiene was interesting, as these congresses always are, for they deal with so many practical everyday questions. The most remarkable, and at the same time a very discouraging, feature about the congress was the utter collapse of the Bacteriological Section. A joint meeting with the Third or Sanitary Engineering Section had been organised. The engineers appealed to the bacteriologists to indicate how towns should be supplied with water: should it be spring water, river water, water from the chalk, filtered water, or water sterilised by some chemical or electrical process? The result of the debate that ensued must have greatly increased the perplexities of the engineers, for there was no agreement among the bacteriologists on any one of the points raised. All these debates were described at length in our columns at the time and we also published briefer accounts of minor congresses, such as the international congresses on psychology, on sanitation in the colonies, on pharmaceutical specialities, &c.

The Universal Exhibition.

Then, as far as time, space, and the intervals between these congresses would allow, we gave descriptions and criticisms of the medical, surgical, and sanitary sections of the Universal Exhibition. This was a difficult task to undertake, for the exhibits were scattered in all directions and their number was legion. Perhaps one of the most remarkable features was the show made by new countries and by the smaller nationalities, such as Hungary and Belgium. Great Britain, on the other hand, was only represented by manufacturers of sanitary appliances, &c. There were no Government, State, or municipal exhibits to show what general progress in sanitation had been accomplished in the United Kingdom. The Governments of almost all the other nations had, on the contrary, sent reports, diagrams, and various models of institutions, bacteriological laboratories, &c., which indicated what had been accomplished in recent years for the preservation of public health and for the spread of the knowledge of hygiene. If the political action of the British Government has of late years been the subject of much hostile criticism on the continent, the really wonderful demonstration in which representatives of all nations participated and which was organised by the French medical men in honour of Lord LISTER was a proof that the civilised nations of the world are ever ready to acknowledge, and to pay homage to, what has been achieved in Great Britain for the advancement of science. It is a pity, therefore, that the authorities in this country did not profit by the Universal Exhibition to show more fully how in matters of sanitation we are still in the vanguard. Such an effort would have been fully appreciated. For throughout the proceedings, whether at the Exhibition or in the congresses, whenever an Englishman presented himself he was received with the greatest courtesy and was generously awarded whatever praise or applause was suited to his endeavours and work. Indeed, all such exhibitions and international congresses must tend to smooth rough corners and to build up international friendships and alliances, as well as to spread knowledge and to give birth to new ideas. Thus is the course of peace and progress advantageously served.

THE ORGANISATION OF THE PROFESSION.

Continuing this year the campaign started by the series of articles entitled "The Battle of the Clubs" and "Hospital Abuse" we have published further articles on the Organisation of the Profession, which were the result of investigations made by our Special Commissioner at Cork, Yarmouth, Norwich, and Cowes. It was at Cork that the movement against the clubs definitely began, and there the members of the profession have united with wonderful unanimity. At first they attempted to utilise what professional organisations already existed, but experience soon proved that to meet new conditions and to enforce a new policy it was necessary to create a special organisation. Thus the Medical Profession Association of Cork came into existence. So far back as 1892 the majority of the Cork practitioners had agreed on a wage-limit to be enforced for all contract work, and the following year they undertook to boycott those practitioners who failed to stand by the profession. It was not, however, till February, 1895, that the celebrated movement against the medical aid clubs began. Then nine medical officers resigned the positions which they held in connexion with 20 clubs. The clubs succeeded in importing four outside medical men and a long struggle commenced. But the Cork Medical Profession Association were able to raise a fund, which, however, was not needed for more than a year, as the position of the medical men greatly improved through the abolition of former abuses. Gradually the resistance has decreased, only 12 out of the 20 societies continued the struggle and only two out of the four imported medical men remained to help them. With impoverished exchequers and reduced membership these clubs still continue the struggle. The practitioners of Cork, however, have long since become quite independent of them and their members, for the position of the practitioners has in every respect been greatly improved through the successful action of their organisation.

At Great Yarmouth also the resident medical practitioners have given a good example of what can be done by united action. There they have fought the Medical Institute established by a federation of friendly societies. Constituting themselves into a branch of the Incorporated Medical Practitioners' Association, they first attempted to prevent the formation of female lodges of Foresters and the importation of practitioners by medical insurance companies. To secure union in the ranks of the profession the older practitioners were careful to befriend and to assist their juniors in every way and thus prevented the latter from falling into the hands of the organisations that were seeking to exploit and to sweat medical men. The profession was successful in rendering it impossible for speculative insurance companies to establish branches of their business in Yarmouth. Several clubs that have not joined the institute have accepted the terms offered to them by the Yarmouth practitioners. Altogether the latter are now in a much more favourable position and many of the abuses have been done away with. Contrary to the usual experience, it was not the practitioners who struck against the clubs but the latter organised a lock-out. The clubs called upon the practitioners to accept the conditions which the clubs had thought fit to impose or to resign their posts of medical officers to these institutions. The resignations followed in due course and thus the lock-out began and it has worked to the great moral and material advantage of the members of the profession in practice at Yarmouth.

In the neighbouring town of Norwich, however, no such favourable results have been attained. Meetings were held, excellent resolutions were adopted, but there has been no spirit of discipline and what was voted was never carried out. 25 years ago similar efforts were made and with as little success. What the medical practitioners collectively condemn they individually practise. They denounce the club and contract system and yet they nearly all work for clubs or contract with patients—that is to say, have penny clubs of their own. A good leader and a powerful organisation are required. At present neither is forthcoming. Much of what our Commissioner has seen and described is encouraging; but his experiences at Norwich were the reverse of this. In one respect Norwich has set a good example; the members of the profession in that town have displayed a true spirit of solidarity towards their colleagues of the neighbouring town of Yarmouth. None of the Norwich *consultants consented to meet the practitioners of Yarmouth* who were working for the Friendly Societies Medical Institute in that town. They have been equally staunch in refusing to have anything to do with the medical officers who are the salaried servants of the Norwich Friendly Societies Medical Institute. When any member of this institute desires a second opinion he must visit a consultant alone and pay a guinea fee, and the fact that many members have done this shows that they can afford more than a penny per week for medical attendance.

At Cowes also there have been much weakness, hesitation, and backsliding displayed by the local practitioners. One local practitioner, however, has made a good fight against the gross abuse prevailing among the friendly societies. It was especially against the female lodges of Foresters that the contest arose and in the course of time a wage-limit was imposed. This wage-limit is too high and there is no really effective machinery to ensure that it shall be observed; but still, it is something to have established the principle and to have made the majority of the local practitioners acknowledge the necessity of some form of united action to secure such reforms. This wage-limit, however, does not apply to the *Foresters Friendly Society, but only to the medical aid* society which the Foresters have formed for the benefit of their wives and other members of their families. Both the Oddfellows and the Foresters retain in their ranks many prosperous members who can well afford to pay the usual medical fees. There is evidently urgent need for the formation of a medical union for the whole of the Isle of Wight.

This principle of forming medical unions was endorsed at Manchester, where in the month of May a conference on the Organisation of the Profession was held under the auspices of the Manchester Medical Guild, which is a medical union formed by some 200 medical men. 50 delegates attended and claimed to speak on behalf of about 4000 practitioners. This would be a very good beginning indeed if the practitioners in question were not merely sympathetic but were solidly organised Unfortunately the conference *spent the greater part of its time in describing* well-known grievances instead of devising means of action. Then there was weakness displayed in the tendency to call upon others to do the work which the medical practitioners should themselves be the first to undertake. Parliament was to legislate in this direction and in that direction, and the General Medical Council was to enforce new ethical rules for the government of the profession. But reforms do not come this way, and authorities rarely do more than give official sanction to what has already, at least in part, been achieved by voluntary effort. The first step of all is organisation, legislation will follow in due course upon united action.

HONOURS TO MEDICAL MEN.

The closing year of the nineteenth century has been an average one in respect of the number of honours which have been bestowed upon members of the medical profession. At a time when Imperialism and all that is connoted in that word was, and is, so much in the air it was perhaps fitting that the list *of honours for the new year,* like the subsequent birthday honours, should embrace the names of men widely distributed over Her Majesty's dominions, and so we find it. Among the new Knights were Sir T. LAUDER BRUNTON, M.D. Edin., F.R.S., and Sir F. H. LOVELL, C.M.G., Surgeon-General of Trinidad, the former a physician of high standing, and a man who has unobtrusively worked hard in the profession to which he belongs; the latter a member of the Executive and Legislative Council of Trinidad, who at one time held the appointments of chief medical officer, President of the General Board of Health, and member of the Legislative Council of Mauritius; and the Honourable Sir JOHN ALEXANDER COCKBURN, M.D. Lond. and Adel., Agent General in London for South Australia, formerly Premier of that colony, received knighthood in the Order of St. Michael and St. George. Mr. JOHN PRINGLE, M.B., C.M. Aberd., a member of the Privy Council and Legislative Council of the Island of Jamaica; Mr. PATRICK MANSON, M.D., LL.D. Aberd., medical adviser to the Colonial Office; Mr. WORDSWORTH POOLE, M.B., B.C. Camb., late principal medical officer of the West African Frontier Force, now Legation surgeon at Peking; and Mr. ARCHIBALD DONALD MACKINNON, M.D. Aberd., principal transport officer for Uganda, were appointed Companions of the Order of St. Michael and St. George.

The disappointingly short list of birthday honours added four new knighthoods to the profession, namely, those of Sir HECTOR CAMERON, the President of the Faculty of Physicians and Surgeons of Glasgow and the representative of that body upon the General Medical Council; Sir J. W. MOORE, the President of the Royal College of Physicians of Ireland; Sir WILLIAM BISSET BERRY, Q.C., Speaker of the House of Assembly of the Cape of Good Hope; and Sir DAVID PALMER ROSS, C.M.G., Surgeon-General of British Guiana. Lieutenant-Colonel AYLMER MARTIN CROFTS, I.M.S., residency surgeon at Gwalior and medical officer to the Maharajah, received *a Companionship of the Most* Eminent Order of the Indian Empire. Companionships of the Bath were bestowed upon Surgeon-General H. SKEY MUIR, Deputy Director-General of the Army Medical Service, and Lieutenant-Colonel B. B. CONNOLLY, late of the same service. Lieutenant-Colonel R. N. CAMPBELL, I.M.S., and Captain C. H. JAMES, I.M.S., received the Kaisar-i-Hind gold medal for Public Service in India. Major STEVENSON, I.M.S., Captain JOHN GRANT, I.M.S., and Miss CHARLOTTE ADAMS, L.R.C.P. Edin., Mrs. HENRY SMITH, and Miss SUSAN CAMPBELL, L.R.C.P. Edin., also received the silver medal of the same order.

Sir GEORGE HARE PHILIPSON, M.D. Cantab., M.D., D.C.L. Durham, President of the University of Durham College of Medicine and representative of that College on the General Medical Council, was created a Knight this year.

In 1899 the German EMPEROR conferred upon Surgeon-General J. JAMESON, C.B., the medal instituted in memory of the late Emperor WILLIAM for services in connexion with the Franco-German war. We are pleased to have to record that this year the KAISER has conferred upon Sir WILLIAM MAC CORMAC the "Kaiser Wilhelm" memorial medal in recognition of his services during the same war of 1870–71. Sir WILLIAM MAC CORMAC has also received from the President of the French Government the Cross of Commander of the Legion of Honour in recognition of similar services.

During the year Lord LISTER has been appointed Serjeant-Surgeon in Ordinary to Her Majesty, in the room of Sir JAMES PAGET, Bart., deceased, and Mr. FREDERICK TREVES has been appointed one of the *Surgeons Extraordinary* to Her Majesty.

We close our list of honours to British subjects with a name of which we and the whole of the profession feel proud in the highest degree—namely, that of Major WILLIAM BABTIE, C.M.G., V.C., of the Royal Army Medical Corps, who has received the decoration of the Victoria Cross for the following act of courage. At Colenso, on Dec. 15th, 1899, the wounded of the 14th and 66th Batteries Royal Field Artillery were lying in an advanced donga close in the rear of the guns *without any* medical officer to attend to them, and when a message was sent back asking for assistance Major W. BABTIE rode up under a heavy rifle fire, his pony being hit three times. When he arrived at the donga, where the wounded were lying in sheltered corners, he attended to them all, going from place to place exposed to the heavy rifle fire which greeted anyone who showed himself. Later in the day Major BABTIE went out with Captain CONGREVE to bring in Lieutenant ROBERTS who was lying wounded on the veldt. This also was under a heavy fire.

It is somewhat invidious to select from the names of foreign medical men those who have received honours of distinction during the year, but we may perhaps mention the name of Dr. R. BLONDEL, who so ably acted as General Secretary to the International Congress of the Medical Press which was held in Paris during the time of the Exhibition and who was named a Chevalier of the Legion of Honour.

OBITUARY.

Again we have to present to our readers a summarised account of those members of the medical profession who have finished their labours in this life. As the members of the navy and the army serve in all parts of the empire to guard the interests of the body politic, so, too, the members of the medical profession serve in very varied fields to guard the interests of the human body. As sickness and wounds are universal, so, too, are those trained to do their utmost to prevent and treat the one or to heal the other found throughout the world. The first name on our list, first in reputation, in honours, and in date of occurrence, is the honoured one of Sir JAMES PAGET, who passed away full of years and honours on the night of Dec. 30th, 1899. His labours and example for good are known to all the world.

Naval Medical Service.

The senior service has suffered less by death among its medical members than the junior, but we have to chronicle the death of HENRY PEACOCK, F.R.C.S. Eng., M.R.C.P. Lond., of Bath, who served in the Royal Navy on board H.M.S. *Crocodile* from 1839 to 1840, and for 20 years afterwards as medical officer of the dockyard at Chatham. In 1862 he retired from the service and started in practice at Sudbrook, Gloucestershire. He was subsequently assistant physician to the Gloucester General Infirmary. Lieutenant-Colonel ARCHIBALD ADAMS entered the medical department of the Navy in 1872 and served with the Royal Marines through the Ashanti war of 1873–1874. In 1875 he entered the Indian Medical Service, and after being attached to the Erinpoora force received the appointment of residency surgeon to the Court of Marwar, where he resided for 18 years. After this he was made administrative officer in Rajputana and died while combating an epidemic of cholera. He became Lieutenant-Colonel in 1895. GEORGE HUTCHINSON MILNES, M.D. Cantab., M.R.C.S., entered the Royal Navy as surgeon in 1886, served at Suakim, and afterwards at the Royal Naval Hospital at Haslar.

Army and Indian Medical Services.

In the Army Medical Service we have to note the deaths of ALEXANDER GRANT, F.R.C.S. Edin. Mr. GRANT entered the Bengal Medical Service in 1840 and retired as surgeon-major in 1861. He served through the Chinese war of 1841–42 and also through the first Sikh war. In 1849 he was appointed surgeon to the Governor-General. He held the post of President of the Medical Faculty in the University of Calcutta and was also an honorary surgeon to the QUEEN. DAVID CULLEN, M.D. Edin., a deputy-surgeon-general of the Army Medical Department, served through the Crimea and the Mutiny. From 1875 to 1880 he was registrar to Netley Hospital. He held the Crimean and Mutiny medals, with clasps for Sebastopol and Lucknow. ROBERT COLLUM, M.D. Glasg., M.R.C.P. Lond., entered the Bombay Medical Service in 1837 and was attached to the staff of Sir CHARLES NAPIER during the conquest of Scinde. Between Bombay and Scinde he had to deal with an outbreak of cholera on board the ship from which 64 soldiers died in eight days. Whilst in Scinde he had medical charge of the troops returning from the first Afghan war and afterwards served as surgeon to their Highnesses the ex-Ameers of Scinde. After further service in Bengal and Bombay he retired from the service in 1857. During his residence in England he was physician accoucheur to the Paddington Maternity Charity and physician to the Western General Dispensary. CHARLES POPE WALKER, M.B. Durh., major in the Royal Army Medical Corps, fell a victim to dysentery at Ladysmith on Jan. 5th. He went out with the troops in November, 1899, and was present at the battles at Dundee and Elandslaagte. He entered the army in 1886 and first served in the North-West Provinces. ALEXANDER CHARLES ARCHIBALD ALEXANDER, M.R.C.S. Eng., was a major in the Royal Army Medical Corps and died on Jan. 23rd. He first saw service in Egypt with the Guards at Suakim in 1885, receiving the medal with clasp for Hasheen and Tamai together with the Khedive's star. He was permanent medical officer to the Royal Military Tournament, and was only prevented from accompanying the forces to South Africa owing to the effects of a sunstroke received at Gibraltar last year. THOMAS GUY, M.D. Heidelb., F.R.C.P. Lond., was born in 1819 and entered the army in 1842 as assistant surgeon. He became surgeon in 1853 and surgeon-major in 1862. He served through the Abyssinian war of 1867–1868, was mentioned in despatches, and was promoted to be Deputy-Inspector-General of Hospitals. In 1872 he retired with the honorary rank of Inspector-General. During the Franco-German war he acted as director of the English ambulance. WILLIAM MCNEILL WHISTLER, M.R.C.P. Lond., was educated at the University of Pennsylvania, and though not serving with the British army acted as assistant surgeon with the Confederate army in the American Civil War. At the conclusion of hostilities he came to London and after studying at St. George's Hospital was appointed physician to the London Throat Hospital. HENRY THOMPSON, M.R.C.S. Eng., L.R.C.P. Lond., practised for many years in the north of England and was for long connected with the Hull Infirmary, being successively house surgeon, assistant surgeon, and full surgeon to that institution. He was also for 20 years surgeon to the 1st Volunteer Battalion East Yorks regiment and was promoted on his retirement to the rank of surgeon-lieutenant-colonel. THOMAS ALFRED PERRY MARSH, L.R.C.P. Lond., M.R.C.S. Eng., died from enteric fever at Deelfontein on May 22nd. He was educated at Bristol and University College Hospital, and entered the Army Medical Service in about 1882. He served through the Burmese war of 1885–1887, and previously to his illness was principal medical officer at De Aar. At the time of his decease he was a major in the Royal Army Medical Corps. AYLMER ELLIS HAYES was at his death lieutenant-colonel in the Royal Army Medical Corps. He was educated at St. Mary's Hospital and became M.R.C.S. Eng. in 1871. He joined the Army Medical Staff, becoming surgeon in 1877, surgeon-major in 1889, and lieutenant-colonel in 1897. He served through the Afghan war of 1878–1880, for which he received the medal. Later he served in the Soudan, being twice mentioned in despatches and winning the D.S.O. After spending some time at Netley as registrar and at Aldershot in command of No. 2 Station Hospital he served at Hong-Kong, but in 1897 retired from the active list. On the outbreak of the present war he re-joined and was put in charge of the Connaught Hospital. JOHN STEWART STEVENSON, M.R.C.S. Eng., L.R.C.P. Lond., who died at Lucknow from heat apoplexy, entered the Indian Medical Service in 1896, and shortly after his arrival in India was sent to Bangalore on plague duty. He also served as "special plague officer" in the Mauritius. He served with the Tirah field force during the operations on the North-west frontier in 1897-98 and received the medal and clasp. He was the only son of Surgeon-General W. F. STEVENSON, who recently returned from South Africa, where he had been acting as principal medical officer on the line of communications. CHARLES JAMES HISLOP WARDEN, Lieutenant-Colonel I.M.S., was for many years a prominent chemist and pharmacologist in India. He qualified as M.R.C.S. Eng. in 1872 and L.R.C.P. Lond. in 1873 and took the M.D. degree of Brussels in 1884. At the time of his death he was examiner of medical stores to the India Office. He joined the Bengal Medical Service in 1874. JOHN TRESSILIAN TOLL, M.R.C.S. Eng., L.R.C.P. Edin., practised for some time in Australia. When the first South Australian contingent started for the front he volunteered as medical officer and was appointed with the rank of surgeon-major. He accompanied the troops to Bloemfontein, where he was attached to a hospital and was stricken with enteric fever. Becoming convalescent he started for home but died on the voyage.

Ambassadorial and State Officials.

EDWARD DALZEL DICKSON, M.D. Malta, was physician to the British Embassy at Constantinople, in which city he lived for 60 years. He was the eldest son of a naval surgeon who served under NELSON in the Baltic campaign. EDWARD DICKSON was born in 1816 and was educated at the University of Malta. In 1837 he was appointed physician to the British Consulate at Erzeroum. He was appointed Embassy physician at Constantinople in 1856 and ten years later served as third commissioner at the International Conference held in that city to inquire into the best means of preventing the spread of cholera from Asia into Europe. HADLEY JACKSON, M.R.C.S. Eng., L.R.C.P. Lond., who died from fever in the Uganda Protectorate on Feb. 16th, was educated at University College Hospital and served in Northern Rhodesia. Later he took service under the Uganda Protectorate and was in medical charge of a punitive column when he met his death. EDWIN VAN MILLINGEN, M.D. Würtzburg, practised in Constantinople as an ophthalmic and aural surgeon. He was an Englishman, but received his medical education at Würtzburg and Vienna. He was professor of ophthalmology in the Imperial School of Medicine at Constantinople. His Excellency ROBERT HALLIDAY GUNNING, M.D., LL.D. Edin., was educated at Edinburgh, but spent most of his life in Brazil where he was a great favourite of the late Emperor. The country has also to regret in the person of Mr. ARTHUR JENNER, murdered in Somaliland, a public servant connected by birth with the medical profession. Mr. ARTHUR JENNER was one of the sons of Sir WILLIAM JENNER.

University and College Professors.

The universities have this year suffered greatly by the loss of prominent professors. The University of London led the way in having to mourn the death of Sir JAMES PAGET, who, though not a professor, was Vice-Chancellor from 1884 to 1895. Next in order the University of Edinburgh lost by death the valuable services of her Professor of Physic and of Clinical Medicine, Sir THOMAS GRAINGER STEWART, in his sixty-third year. He succeeded Sir R. CHRISTISON as physician-in-ordinary to HER MAJESTY the QUEEN in Scotland, was knighted in 1894, and was President of the British Medical Association in 1898. An admirable clinical teacher, he worthily sustained the best traditions of Scottish medicine. But a few weeks after the death of the Professor of Medicine the University of Edinburgh had to sustain another blow by the death of Sir ANDREW DOUGLAS MACLAGAN, the Professor of Jurisprudence and Public Health. He came of a medical stock, his father, DAVID MACLAGAN, having been surgeon-in-ordinary to the QUEEN in Scotland, physician to the forces, and President of both the Royal Colleges of Edinburgh—a double honour which his son DOUGLAS likewise filled. Sir DOUGLAS MACLAGAN, who was knighted in 1886, was not only an eminent physician, surgeon, and medical jurist, but also a good writer and musician. He appeared for the defence of MADELEINE SMITH in her trial in which a verdict of "Not proven" was returned. Sir WILLIAM PRIESTLEY, Professor of Midwifery and of Diseases of Women and Children at King's College, London, died, after a long illness, on April 12th. He attended sundry members of the Royal family at the time of their confinements and was knighted in 1893. In 1896 he was elected without a contest as Member of Parliament for the united Universities of Edinburgh and St. Andrews, and although he had but a brief career in the House, yet he was able to exercise an important influence in relation to measures bearing on public health. PIERCE ADOLPHUS SIMPSON, M.D. St And., was Emeritus Regius Professor of Medicine in the University of Glasgow. He had also been lecturer on medical jurisprudence at Anderson's College and physician to the Glasgow Royal Infirmary. JOHN ANDERSON, M.D., LL.D. Edin., F.R.S., went to India in 1864, when he was appointed professor of Comparative Anatomy in the Medical College, Calcutta. Between 1868 and 1887, when he retired, he accompanied various Government expeditions as scientific adviser. By the death of Sir HENRY ACLAND, the University of Oxford lost a very familiar and well-beloved personality. Full of years and honours the former Regius Professor will live long in the recollection of the University which he loved so well. ALFRED WILLIAM HUGHES, M.B., C.M. Edin., F.R.C.S. Eng. and Edin., Professor of Anatomy at Cardiff, and afterwards at King's College, London, went out to the war in charge of the Welsh Hospital. He contracted typhoid fever and only reached home to die. DENNIS EMBLETON, M.D. Durh. and Pisa, F.R.C.S. Eng., F.R.C.P. Lond., who died in his ninety-first year, was the first professor of medicine in the University of Durham, and from 1858 to 1872 represented that university on the General Medical Council.

Hospital Physicians and Surgeons.

ROBERT GLASGOW PATTESON was educated at Dundalk Grammar School and at Trinity College, Dublin, where he graduated as M.B. in 1885. In 1886 he was elected surgical travelling prizeman of Trinity College and pursued his studies at London, Berlin, and Vienna. He was afterwards assistant surgeon at St. Vincent's Hospital and in 1895 was elected surgeon to the Meath Hospital. He was but 38 years of age at the time of his death. GEORGE VINER ELLIS, F.R.C.S. Eng., was born in 1812. He received his early education at the Cathedral Grammar School of Gloucester and afterwards at University College, London, where he was appointed demonstrator of anatomy to RICHARD QUAIN. He studied in Paris and Berlin, and in 1850 was appointed Professor of Anatomy at University College in succession to RICHARD QUAIN, which post he held until 1877, when he was made Emeritus Professor. He was the author of the well known "Demonstrations of Anatomy." JOHN NEVILLE COLLEY DAVIES-COLLEY, M.A., M.B., M.C. Cantab., F.R.C.S. Eng., was born at Chester in 1843 and was educated privately and at Trinity College, Cambridge. In 1864 he entered Guy's Hospital as a medical student, graduated as M.B. in 1868, and became a Fellow of the Royal College of Surgeons of England in 1870, being also appointed demonstrator of anatomy in the Guy's Hospital Medical School. In 1872 he was elected assistant surgeon and during the course of his career at the hospital was demonstrator of surgery, lecturer on surgery, lecturer on anatomy and full surgeon. He was also for a long time surgeon to the Seamen's Hospital, Greenwich. On becoming aware, about Christmas, 1899, that he had malignant disease of the liver he resigned his post at the hospital and was presented by the students with an illuminated address. He was a noted consultant, a good surgeon, and an admirable teacher. GEORGE EDWARD WILLIAMSON, M.A. Durh., M.B. Lond., F.R.C.S. Eng., was one of the many medical men whose deaths Newcastle-on-Tyne has recently had to deplore. He was born in 1842 and was educated at the London Hospital and in Paris. In 1878 he was admitted F.R.C.S. Eng., and practised as an ophthalmic surgeon, being for some years ophthalmic surgeon to the Royal Infirmary, Newcastle. For a few months before his death, however, he was engaged in teaching operative surgery as a colleague of Professor F. PAGE. JULIUS ALTHAUS, M.D. Berlin, M.R.C.P. Lond., was the son of a German Lutheran Minister and was born at Detmold. He studied at Bonn, Heidelberg, Berlin, Vienna, Paris, Prague, and London, in which last town he finally settled. In 1866 he founded the Hospital for Epilepsy and Paralysis in Regent's Park to which institution he acted as physician for 28 years. JAMES GROSVENOR MACKINLAY, F.R.C.S. Edin., was born in 1844 and was educated at Epsom College and Charing-cross Hospital. He devoted himself to ophthalmic surgery and at the time of his death was surgeon to the Royal Eye Hospital and to the Royal Free Hospital. He was an original Fellow of the Ophthalmological Society. JAMES FENTON STAMPER was for many years in practice at Pembroke Dock. He qualified as M.R.C.S. Eng. in 1861 and took the degree of M.D. at the University of St. Andrews in 1862. He was Admiralty surgeon and agent, a J.P. for the borough of Pembroke, consulting physician to the Haverfordwest and Pembrokeshire Infirmary, and surgeon to the Pembroke Dispensary. BERNARD E. BRODHURST, F.R.C.S. Eng., was well known as an orthopædic surgeon and was for many years on the staff of the Royal Orthopædic Hospital. THOMAS JONES, M.B., B.S. Lond., F.R.C.S. Eng., who died at Springfontein, was one of the many victims, direct or indirect, of the South African war. He had left England on April 14th in charge of the Welsh Hospital and died on June 18th. Born in Carmarthenshire, he was educated at Derlwyn College and afterwards at the Swansea Normal School. He then studied at the Northern Hospital, Liverpool, and at Guy's Hospital. He graduated as M.B. and B.S. at the University of London and became F.R.C.S. Eng. in 1875. Previously to this, however, he had served the Manchester Royal Infirmary as house surgeon, and after holding various posts became full surgeon in 1880. He was also professor of surgery at the Owens College. He was an admirable and most popular teacher and his death is a great loss to the profession. HENRY BURFORD NORMAN, F.R.C.S. Eng., was educated at University College, London, where among his contemporaries were SPENCER WELLS and JOHN ERICHSEN. He started in practice as an ophthalmic surgeon and filled the office of surgeon to the North London Eye Hospital. Failing health compelled him to leave London and he retired to Portsmouth, where he was soon elected a member of the surgical staff of the Royal Portsmouth Hospital. He was one of the founders of the Portsmouth and South Hants Eye and Ear Infirmary and was consulting surgeon to it. DANIEL JOHN LEECH, M.D., F.R.C.P. Lond., was Professor of Materia Medica and Therapeutics in the Owens College, consulting physician to the Manchester Royal Infirmary, and representative of the Victoria University upon the General Medical Council. He was in addition secretary of the Manchester and Salford Sanitary Association, a body which through his instrumentality has been of the greatest service to Manchester as regards the prevention of the adulteration of food and the prevention of black smoke. HENRY EWBANK, M.R.C.S. Eng., L.R.C.P. Edin., was for many years a prominent practitioner in Cheltenham. From 1881 to 1883 he was senior surgeon to the General Hospital, Cheltenham. For some time, too, he acted as honorary surgeon to the Home for Sick Children. WILLIAM MARCET, M.D. Edin., F.R.C.P. Lond., F.R.S., who died at Luxor, was well known as a physician interested in physiological chemistry. His life's work was an inquiry into respiratory phenomena and his results were given to the world in the Croonian lectures delivered by him in 1895. WILLIAM ADAMS, F.R.C.S. Eng., the well-known orthopædic surgeon, was surgeon to the Great Northern Central Hospital. He was the first to practise subcutaneous osteotomy of the neck of the femur for ankylosis of the hip-joint. THOMAS SCATTERGOOD, M.R.C.S. Eng., L.S.A., was for many years connected with the Leeds Medical School. Sir WILLIAM STOKES, M.D., M.Ch. Dub., F.R.C.S. Irel., came of a family eminent in many branches of learning. He was Professor of Surgery to the Royal College of Surgeons in Ireland, surgeon-in-ordinary to HER MAJESTY the QUEEN in Ireland, and had been Honorary President of the International Medical Congresses of Berlin, Rome, and Moscow. In 1886 he received the honour of knighthood and this year he sailed for South Africa as one of the consulting surgeons to the forces. His death occurred at Pietermaritzburg from pneumonia. He had been lecturer on surgery at the Carmichael School and was surgeon to the Meath Hospital. THOMAS MOORE, F.R.C.S. Eng., of Blackheath, was at the time of his death senior surgeon to the Miller Hospital at Greenwich and consulting surgeon to the Brighton Children's Hospital. ROBERT STRAFFORD SMITH, M.D. R.U.I., who died at an early age from septicæmia, was one of the most promising of the younger generation of medical men in Belfast. He was physician to the Royal Victoria Hospital in Belfast and Lord Chancellor's Visitor in Lunacy. LEWIS ALBERT SAYRE, M.D., LL.D., of New York, was the well-known orthopædic surgeon and Emeritus Professor of Orthopædic Surgery of the New York University. WILLIAM CHAPMAN GRIGG, M.D. Edin., M.R.C.P. Lond., who died in South Africa, was for some years a prominent gynæcologist in London. He was obstetric physician to out-patients at Westminster Hospital and physician to Queen Charlotte's Lying-in Hospital. ROBERT CORY, M.D. Cantab., F.R.C.P. Lond., had held the posts of assistant obstetric physician to St. Thomas's Hospital, but he was chiefly known for his admirable work in vaccination and his self-sacrificing heroism in vaccinating himself from an undoubtedly syphilitic child. On three occasions he escaped infection but on the fourth he contracted a severe attack of syphilis. WILLIAM ANDERSON, F.R.C.S. Eng., who died very suddenly on Oct. 27th, was surgeon to St. Thomas's Hospital. He was well known as an authority upon Japanese art and was for some time director of the Japanese Naval Medical College at Tokio. He was also Professor of Anatomy to the Royal Academy of Arts. Genial, kindly, and a thorough artist, his place will be hard to fill.

Civilian Practitioners.

WILLIAM NEALOR THURSFIELD, M.D. Edin., D.P.H. Cantab., was born in Shropshire and educated at Marlborough and at King's College. He subsequently studied at the University of Edinburgh and for one year after his graduation he held a commission at Netley, which he resigned owing to the illness of his father. He then practised in New Zealand, but returning to England took up the subject of public health and was appointed medical officer of health of Wellington, Salop, in 1870. In 1873 he was appointed medical officer to a combination of urban and rural districts, and in 1897 he gave up these district appointments on becoming medical officer of health for the county. JAMES HOWISON, L.R.C.P., L.R.C.S., L.M. Edin., who practised for many years in Darlington, received his medical education at Edinburgh. He died in London at the age of 77 years, and his death was caused by his blindness, owing to which he accidentally stepped off the platform at West Hampstead station and received fatal injuries from a train. John Gorham, M.R.C S. Eng., L.S.A., was for many years a well-known practitioner in Tonbridge and wrote much upon light and crystallography. Frederick Williams Lewis was educated at the Middlesex Hospital and practised in Llandovery, being surgeon to the Great Western and the North-Western Railway Companies. George Cheesman, L.R.C.P. Edin., M.R.C S. Eng., was for a long time medical officer to the Southampton Incorporation, and died at his residence, Bitterne Park, at an advanced age. Joseph Edward Kenny, L.R.C.P., L R C.S. Edin., who received his medical education at Dublin and Edinburgh, took an active part some two years after qualifying in endeavouring to stamp out an epidemic of small-pox which was raging in Dublin. He was a prominent Irish Nationalist, and in 1881 was arrested as a "suspect." He was a firm supporter of Mr. Parnell and stuck to him even after the split which arose in Committee Room 15. Although so active a politician he took the greatest interest in charitable work in the city of Dublin, and was in addition coroner for the city, discharging the duties of the office with great ability and success The cause of his death was septicæmia. Sir William Miller, M B T.C D., was one of the best known practitioners in Ulster. In 1875 he was chosen Mayor of Derry, was re-elected in 1876 when he was knighted, and was again re-elected in the following year. He was also Mayor in 1888 and in 1889 and at the time of his death had only just been appointed high sheriff of the county. Besides his public appointments, which were very numerous, he had a large private practice. Henry Hannotte Vernon, M.D., F.R S. Edin., had been medical officer of health of Southport since 1873 and since 1888 had devoted the whole of his time to that office. He received his medical education in Edinburgh and for a time practised in London, but had resided in Southport since 1868. Daniel Ainley, L R C.P. Edin, M.R C.S. Eng., was for many years medical officer of health of Halifax. He was educated at St. Bartholomew's Hospital and commenced practice in Halifax in 1868 and was appointed medical officer of health of the borough in 1872 In 1892 and 1893 his department was sorely taxed by an epidemic of small-pox, over 500 persons being removed to hospital. John Wiblin, F.R.C.S. Eng., who died at the advanced age of 87 years, practised in Southampton, where he was sanitary surveyor to the Board of Trade and medical superintendent of quarantine to the Union and Royal Mail lines of steamers. George Bird, M.D. St. And., who practised in Welbeck-street for many years, was born in 1817 and was educated at University College. He was well read and had travelled much and had had many patients from the literary and artistic worlds, such as Leigh Hunt, Dickens, Lytton, Thomas Woolner, and Sir Richard and Lady Burton. Benjamin Howard of New York was a Member of the Royal College of Surgeons of England and a Fellow of the Royal College of Surgeons of Edinburgh. He was well known as the inventor of Howard's system of artificial respiration which he first demonstrated at King's College Hospital on July 7th, 1877. Another subject in which he took a deep interest was the provision of horse ambulances for large towns. David Young, M.D. Aberd., was for many years a well-known practitioner in Florence and in Rome He commenced professional life by holding the professorship of botany at Grant Medical College, Bombay. John Tilsley, M.R.C.S. Eng., L R C.P. Lond., was a medical missionary in China. On the outbreak of the trouble there he started for home but died from dysentery on the day of his arrival in England. George Samuel Gregory, M.R.C.S. Eng., L S A., died in his eighty-fifth year, having qualified in 1835. For 35 years he practised in Stroud, being certifying surgeon under the Factories Acts. He was an intimate friend of Wilkie Collins. Ernest Arthur Taylor Steele, M.R.C.S. Eng., L.R C P. Lond., of Southend, who died at the early age of 34 years, was for some time in practice at Plaistow, Essex, where chiefly owing to his exertions St Mary's Children's Hospital has now reached its present degree of success. John Orton, M.D. T.C.D., was a well-known practitioner at Beeston and the son of a surgeon who was the first English medical man to practise successfully primary amputation at the hip-joint. William Marshall, M.D. St. And., practised for many years in Dumfries. He took a great interest in the Dumfries and Galloway Royal Infirmary and served on its staff for a lengthened period. Alexander Stevenson, M.B, C.M. Glasg., began life as a lawyer, but afterwards took up medicine and practised in South Shields. Samuel Henry Swayne, M.R C.S. Eng., L.S.A., was a member of a well-known medical family in the west of England and practised in Clifton. Richard Hamilton Cowan, M R.C.S. Eng., L.S A, was a prominent practitioner in Wigan and a member of the staff of the Royal Albert Edward Infirmary. Raymond Ferrers Palmer, M.R C S Eng., practised for a few years in Tamworth, but afterwards entered the Dominican Order, devoting the rest of his life to theological and historical research. John Hawthorne, M.D. R.U I., of Banbridge, co. Down; John Quiller Couch, M.R C.S. Eng, L S A., a member of an old Cornish family; and George Cordwent, M.D. St. And., F.R C.S. Eng., who have all passed away during the year, were three well-known personalities in their respective districts. Richard Benjamin Anderson, F.R C.S. Eng., whose troubled life came suddenly to an end from morbus cordis, formerly practised in Tobago, where he was the victim of that gross miscarriage of justice the details of which have been fully set forth in our pages.

Amongst other members of the profession who passed away during the year were Thomas Greaves Walker of Bristol, M.R.C.S. Eng., L.S.A., in his thirty-ninth year; Thomas Jones Dyke, F.R C.S. Eng., for 36 years medical officer of health to the town of Merthyr Tydvil, who died at the age of 84 years; Frederick Edward Pearse, M.D. St. And., medical officer and public vaccinator for the first district of the Frome Union; Robert Goldsworthy Tucker, L R C.P. Edin., M.R.C S. Eng, a well-known practitioner of Swanley in Kent; Samuel Hyde, M.D. St. And., one of the best-known practitioners in Buxton, an original member of the British Balneological Society and for some time editor of its Journal; John William Young Howison Lavies, L F.P.S. Glasg., who died from pneumonia at the early age of 46 years; John Cadwaladr Williams, M.B., C.M. Edin., who also died from pneumonia; Allan McLean, M.D., C.M. Edin., a leading practitioner in Dorsetshire and a keen volunteer who had been commanding officer since 1885 of the 1st Dorset Volunteer Artillery; Joseph Cave Spicer Jennings, F.R C S. Eng., of Malmesbury, a well-known antiquarian; John Underwood, M.D. Edin., of Hastings, who died at the age of 84 years; Walter Clegg, M.R.C S. Eng., L.S.A., who had served in the Crimea and was coroner of the Boston District of Lincolnshire for 40 years; Robert Wills Soper, M R C.S Eng., of Dartmouth, who had held, amongst other appointments, that of Admiralty surgeon and agent and who was a justice of the peace for Dartmouth; Francis Joseph Mathews, L R.C.P. Irel., who died from tetanus after a bicycle accident and who had been for many years medical officer to the Stradone Dispensary District of Cavan and medical attendant to the Royal Irish Constabulary; Thomas Fitz-Patrick, M.D. Dub, M R C.P. Lond., who was a distinguished graduate of Dublin University as well as of Cambridge and a talented physician and remarkable linguist as well as a good scholar; W. Radford, M.D. T.C.D., who died at the advanced age of 89 years and who was a well-known practitioner in the West of England and justly respected for his charitable work in connexion with lace workers, whom, when they complained of failing sight, he used to see personally, to test their refraction, and to supply them with spectacles free of charge; and Claude Clarke Claremont, who qualified as M.R C.S. Eng. in 1855 and served for many years as public vaccinator to the parish of St. Pancras. To Richard Neale, M D. Lond., the medical profession owes an incalculable debt for his arduous labours in the issue of the "Medical Digest." Joseph Mortimer Granville, M.D. St. And., was formerly editor of the *Globe*, and for many years a member of the staff of The Lancet. Roger Edwards, M.D. Durh., was a prominent practitioner in North Wales and several times Mayor of Llanfyllin. We must also mention the names of Thomas Frederick Hale, M.R.C.S. Eng., L.S.A., of Chesterfield; Alexander Deas Davidson, M.D. Cantab., M.R.C.S Eng., ophthalmic surgeon to the Swansea Eye Hospital; and Courtenay Charles Parsons, M.R.C.S. Eng., who went out to the war as a civil surgeon and died from enteric fever.

Deaths of Medical Men serving in the South African War.

The following is a list, complete as far as possible, of those medical men who have been killed or who have died from disease during the present year while serving in South Africa. Some of the names will be seen to be included under other headings in previous paragraphs. Lieutenant Hugh Bernard Onraet, R.A.M.C., was killed on Feb. 27th in the attack on Pieter's Hill; Captain R. H. E. G. Holt, R.A.M.C., died from wounds received during Sir R. Buller's operations at Modder river on Feb. 21st; Lieutenant G. W. G. Jones, R.A.M.C., died from enteric fever on Feb. 20th at Ladysmith; Major Charles Pope Walker, R.A.M.C., died at Ladysmith from dysentery on Jan. 5th; Captain G. S. Walker, R.A.M.C., died from enteric fever at Ladysmith on Feb. 23rd; Major James Minniece, R.A.M.C., died from enteric fever at Pietermaritzburg on March 17th; Lieutenant Hall, Volunteer Medical Corps, died at Mooi river on March 20th; Lieutenant G. H. Irvine, R.A.M.C., attached to the Royal Horse Artillery, was killed at Sanna's Post; Assistant-Surgeon Jackson, 21st Battery F.A., died from typhus fever and dysentery at Pretoria (*circ.* end of March); Civil Surgeon Whicher died from enteric fever at Mooi river on April 27th; Captain H. Esmonde Dowse, R.A.M.C., died at Bloemfontein on May 5th from enteric fever; Dr. T. W. Illingworth, I.Y., died at Boshof from accidentally taking an overdose of morphia while suffering from fever; Captain R. Fawssett, R.A.M.C., attached to the 2nd Life Guards, died from dysentery at Bloemfontein on May 7th; Lieutenant E. L. Munn, R.A.M.C., died from enteric fever at Boshof on May 23rd; Major T. A. P. Marsh, R.A.M.C., died from enteric fever at Deelfontein on May 22nd; Mr. F. R. Eames, a dresser attached to the Welsh Hospital, died from dysentery at Bloemfontein on May 27th; Civil Surgeon Robert Irvine, at Ladysmith, died from enteric fever on May 26th; Civil Surgeon H. Bryant died from enteric fever at Bloemfontein on June 7th; Civil Surgeon R. T. Fitzhugh died from enteric fever at Deelfontein on June 15th; Civil Surgeon E. Smith died from enteric fever at the base hospital on June 16th; Civil Surgeon H. D. Davis died at Springfontein on June 15th; Mr. Thomas Jones, F.R.C.S. Eng., chief of the Welsh Military Hospital died *circ.* middle of June; Surgeon-Lieutenant-Colonel James Stevenson died at Cape Town on June 19th; Surgeon-Lieutenant-Colonel James Creagh, 9th Battalion King's Royal Rifle Corps (North Cork Militia), died from enteric fever on July 6th, between Viljoen's Drift and Kroonstad; Surgeon-Lieutenant-Colonel William Wellington Lake, M.M.C.S., Volunteer Company Royal Army Medical Corps, died at Bloemfontein of Bright's disease on July 13th; Major George Hilliard, C.M.G., R.A.M.C., died at the General Hospital, Newcastle, South Africa, on Sept. 7th, from a gunshot wound in the abdomen; Civil Surgeon A. E. Elliott died at Middelburg on Dec. 1st, and Civil Surgeon C. C. Parsons at Harrismith on Dec. 2nd, both from enteric fever; and Civil Surgeon Englebach was killed in action at Nooitgedacht on Dec. 13th.

This is the tale of losses in our profession for the closing year of the century. The list is a long one and serves once more to emphasise the universality of the services of medical men. In all climes and at all ages they end their life's work. Ours is the only profession which sets out to fight with an enemy which every member of us well knows must win in the end, and yet although the words of Seneca, "Quotidie morimur: quotidie demitur enim aliqua pars vitae," are still true, yet no less true is the saying of St. Augustine that death is "Instrumentum per quod transiretur ad vitam."

Annotations.

"Ne quid nimis."

RETREATS FOR INEBRIATES.

One of the last official acts of the late Home Secretary was the promulgation of rules for retreats licensed under the Inebriates Acts, 1879 to 1899, the text of these rules appearing in the *Gazette* of Dec. 11th. They are drawn up in accordance with the provisions of the Act of 1898, which, although dealing in the main with criminal inebriates and inebriate reformatories, contains several clauses having reference to the less public institutions, amending the Habitual Drunkards Act, 1879, in certain particulars. The general outcome of this amending legislation is to place inebriate retreats on a more stable footing and to put them in some respects under the jurisdiction of the Home Office whose inspector will visit and report upon the manner of their working. This is all to the good and it is a step in advance in the legislative control of the habitual drunkard, who requires as much protection from himself as the community requires from those who are mentally deranged. We say that it is one step, for although the Act of 1898 does not go all the way in the desired direction by enforcing compulsory isolation upon every victim of the drink habit, but only on those who are convicted of crimes (including the "crime of drunkenness"), it does provide for the detention for a certain space of any inebriate who voluntarily submits to treatment; and to all intents and purposes the provisions for such safe and kindly helping of those persons are similar to those which have long been in operation in regard to the insane. As we read the regulations we find but little variation from the rules laid down by the Lunacy Commission for the control of licensed houses, and we are of opinion that in framing these rules the Home Secretary was to some extent guided by the regulations of that body. It may be of interest to review briefly the chief of these rules. The Act of 1898 transfers the licensing authority to the borough or county council, but before application is made to such local authority "by any person or persons desirous of obtaining a licence to conduct a retreat under the Inebriates Acts" plans of the proposed building must be submitted to the Secretary of State for the Home Department for his approval. We observe that it is especially provided that dormitories should show 600 cubic feet of air space per head and separate bedrooms at least 720 cubic feet, and that separate rooms should be set aside for cases of illness. Another provision is that the resident licensee of a retreat shall, wherever possible, be a registered medical man. We heartily approve of this regulation. The inebriate requires often the most careful medical supervision, and, although it does not seem to be explicitly so stated, the general tenour of the rules is such as to imply that where the licensee is not a member of the medical profession there must be a qualified medical attendant who, we think, should reside on the premises. The licensee is required to keep registers and case-books in which entries as to the history and progress of the case and its treatment are to be made, it being, further, his duty to ascertain and to record particulars of the patients after they have been "licensed or discharged." We imagine that this information, which is to be appended to the notes in the case-book, will in many cases be very scanty, and that the record "not heard of" will largely predominate. There is also to be kept a "licensee's journal" in which are to be recorded all matters of importance occurring in the retreat—matters of discipline affecting the servants and patients, and especially facts as to the obtaining of liquor by patients and the measures adopted to prevent recurrence of such infraction of rules. This journal, too, is to contain full details of every circumstance under which any physical restraint or coercion is employed; but we fail to observe any mention of the kind of restraint which may legitimately be adopted. Perhaps the requirement of a full record may suffice to keep such treatment within the narrowest limits, but we would fain have seen, in the interests of the licensee as well as of the patient, some guidance laid down as to the means whereby this exceptional treatment is to be enforced. A "visitors' book" is also to be kept in which the inspector has to enter his observations, of which a copy is to be transmitted to the Secretary of State by the licensee. There are regulations respecting notices of the death and discharge or temporary absence of the patient, to be sent in the one case to the local authority and to the Home Secretary, and in the other to the inspector whose duties are of a highly responsible kind. He can visit the retreat at any time and all parts of it must be open to him, whilst every patient must be produced to him. Whenever required by the inspector "the licensee and the medical attendant respectively shall ... furnish him with a special report upon the mental and bodily condition and conduct with reference to abstinence from intoxicating liquor, or otherwise, of any patient on the register of a retreat." The clause (No. 8) goes on to say that the inspector's annual report "shall be a detailed and independent criticism of the working of each retreat during the year, and if the licensee neglects to provide facilities for employment or allows the establishment to fall below a proper standard of discipline and efficiency, the inspector shall report to this effect to the Secretary of State, who at his discretion will consider the advisability of communicating with the licensing authority." We have quoted these passages in full because they seem to us to be the keystone for the whole of this amended regulation for inebriate retreats. This thorough and independent inspection—a task demanding considerable knowledge and judgment—will, if it is, as it doubtless will be, thoroughly carried out, go far to establish confidence in these desirable institutions. All other regulations are subsidiary although necessary, and we need not dwell upon them here. The essential factor in this, the latest, legislative enactment for the care and control of the habitual drunkard is plainly based on the close affinity between those who give way to intemperance and so are unable to control themselves and those who from mental derangement cannot look after themselves The border line between the inebriate and the insane is a very narrow one and many there be who pass over it. But the reclamation of the drunkard has for its aim the cure of a vicious tendency which if persisted in renders him more fitted for the asylum than for the retreat The "retreat," however, to be effective must be managed as regards personal liberty on much the same lines as an asylum, whilst it recognises the curability of the dipsomaniac and offers him a means of escape from the fate of the hopeless dement.

CHARITABLE BEQUESTS AND DONATIONS IN 1900.

THE *Charity Record and Hospital Times* has carefully added up all the charitable bequests recorded, issue by issue, in its columns and finds that the total reached during 1900 was £2,016,600, as compared with £1,390,136 in 1899, and £1,303,720 in 1898. "At first sight," says our contemporary, "it would appear that with so large an increase in legacies charitable institutions must be in a prosperous state, but in a number of cases the money is left subject to life interests, and in some cases, we are sorry to say, experience has shown that the testators' ideas of their wealth were exaggerated. For instance, in the case of Professor D E. Hughes, who last year left £400,000 to London hospitals, the money will not come to the institutions until 20 years after the death of Mrs. Hughes; and, again, Mr. H. Chester has left about £60,000 in trust to the Haberdashers' Company to be applied to a new hospital at Putney, if it ever be erected; failing such object, after 20 years the income will go to Guy's Perhaps the most curious bequest is that of the late Mr. Alfred Fennings, who carried on a large business as a patent medicine manufacturer and who directed that after the death of his sister the profits of the business should be paid to the National Refuges for Homeless and Destitute Children." The following is an interesting *résumé* of the largest bequests of the year: "Mr. W. Ford (Liverpool), £10,500; Mr. W. W. Pollock (Glasgow), £40,000; Mr. H Vaughan (London), £100,000; Mr. M. Gledhill (Manchester), over £70,000; Rev. W. M. Sutton (Brighton), £14,000; Professor Hughes, £400,000; Mr. S. Redhead (Cheltenham), about £13,000; Mr. S. R. Runz (London), between £80,000 and £90,000; Mr. R Brooke (Scarborough), £13,000; Mr. T. H. Ismay (Liverpool), £10,000; Mr. J. Howgate (Ealing), £8250; Mrs. Leigh (Halifax), £36,000; Mr. G W. Charters (Belfast), £10,000; Miss Cooper (Colchester), £8000 and land for almshouses; Mr. D. Tinslie (Edinburgh), over £200,000; Mrs. Dowling (Bromley), £10,000; Miss E. F. Dalton (Leicester), £40,000; Mr J. Hutton (Leeds), £9000; Mr. Jacob Feis (London), £14,000; Miss E G Price (Canterbury), £10,000; Mr. R. B. West (Exeter), £50,000; Mr. A. Goerz (London), £20,000; Lord Bute, £20,000; Mr. R. Smith (London), £30,000; Mr. J. Downing (London), £15 000; Mr. R Arthington (Leeds), £20,000; Mr R K. Whitehead (Manchester), about £16,000; Mr. W. Matthews, £19,000; Sir H P. T. Barron (Waterford), £30,000; and Mr. J. F. France, £25,000." Dealing with large donations in 1900 the *Charity Record and Hospital Times* points out that though the year just running out witnessed no such gift as that of Sir J. B Maple to the University College Hospital, there are several instances of big donations. "At the beginning of the year Mr. Thomas Aiken gave £40,000 in aid of the funds of the Edinburgh Royal Infirmary, and Mr. George Herring gave £10,000 to the Hospital Sunday Fund of London. Mrs. Ismay, carrying out the wish of her late husband, gave £10,000 to the Liverpool Seamen's Pension Fund, and a further sum of £10,000 was distributed by the trustees of the late Mr B Piercy amongst various charities. Mr. Hartley of Liverpool gave £5000 to the Colne Cottage Hospital and Mr. Astor gave £10,000 to the Maidenhead Cottage Hospital in honour of the coming of age of his son. It was announced at a quarterly court of the London Hospital that Mr. E. L. Raphael had given £10,000 for the endowment of Jewish wards at that institution, and that an anonymous donor had placed

£22,000 in the hands of the governors for the erection of an isolation block. Mr. J. Corbett gave £10,000 to endow the Corbett Hospital at Stourbridge, and within the past few days Lord Mount Stephen has intimated his intention of clearing off the debt on the Aberdeen Infirmary amounting to £25,000." Our contemporary remarks that the London Hospital is the only metropolitan hospital which has had the fortune to secure a big donation, while it will be seen that provincial charities benefit to a much more marked extent in large legacies than do London institutions.

THE BRIGHT SIDE OF MUD.

The unhappy Londoner who at this season of the year walks streets that run with diluted dirt, or even if he drives gets splashed with the spatterings of wheels coming from the opposite direction, is not wont to perceive any benefit in the prevalent mud of his beloved metropolis. Those of us even who love London best admit that we are better out of it when the streets are muddy. For our most important thoroughfares are not very wide and there is no escaping the flying splotches which seem to have a remarkable affinity for those portions of the person or clothing where their presence is least to be desired. Yet, as the title of this annotation suggests, we believe there is a consolation even for the mud-besprinkled. This happy solace is to be found in a comparison between the hygienic effects of mud and its opposite condition of dustiness. Of course mud is, roughly speaking, wet dust, and dust is dry mud; but the evil effects of dust far transcend those of mud. In the dissemination of disease, mud remains comparatively innocent, but for the behaviour of dust in this respect no words can be too strong. Widely disseminated and inevitably inhaled, dust particles carry and deposit enormous quantities of disease. Its local and comparatively trifling damages, conjunctivitis, pharyngitis, and rhinitis, pale before its evil powers in carrying more formidable disorders. It has recently been shown how summer diarrhœa is wont to prevail most where there is most dust, and that dust may contain the dried sputum of phthisical patients is only too familiar to us all. We have mentioned only two of the graver diseases in the distribution and implantation of which ordinary dust plays a leading part. There are still other complaints in which the inhalation of ordinary dust is baneful, not to mention the special diseases caused entirely by special forms of dust, and we would have it borne in mind that mud has no similar evil influence. Mud is largely water. Paradoxical as it may sound mud is clean, at least as compared with dust. Moreover, the ultimate fate of mud is in the drain-pipe of the street, but dust too often ends in the windpipe of a man, if not in the alveoli even of his lungs. In future, then, let us not revile the passing hansom, nor as we wipe from our collar the mud of London's winter streets too fully condemn it; but rather gratefully reflect that a passing inconvenience, a mere temporary disfigurement, is a small price paid for freedom from the evil possibilities of the dust of an apparently brighter day. The ideal street knows neither mud nor dust. But in a world of imperfections let us not too hastily condemn mud. Let us rather congratulate ourselves on the absence of dust.

THE RESIGNATION OF THE MEDICAL OFFICER OF HEALTH OF MERTHYR TYDVIL.

The position of medical officer of health is one of great responsibility, and if the best results are to be obtained by the holder of the office he must have the confidence and the support of the sanitary authority by whom he is appointed. In a large industrial community where members of the authority are so often owners of property which from its very nature frequently comes under the notice of the health department this support is especially necessary, and we believe that in most of the large towns it is ungrudgingly given. We regret to find that otherwise has been the case at Merthyr Tydvil where Dr. C. E. G. Simons, who was only quite recently elected medical officer of health, has felt his position to be so intolerable that he has resigned his office. Dr. Simons was for some years a member of the Merthyr District Council, so it might be supposed that he would be as well acquainted with the temperaments of his former colleagues as they would be with his. With the merits of the dispute which led to the resignation we are not particularly concerned for they were based upon a question of fact as to whether a member of the health committee did or did not make a certain statement which the medical officer considered was a reflection upon his competency. It is, however, within our province to comment upon a condition of affairs the existence of which can only be detrimental to the public generally. In another large district in Glamorganshire the medical officer of health has recently resigned his position, and although there has been no open breach with the local authority it is generally known that they have refused to carry out his recommendations and are now defying the Local Government Board who have urged the acceptance of those recommendations. Surely the time has arrived for the Board to exercise its powers in respect of such sanitary authorities as these.

MULTIPLE ANEURYSMS.

In the *New York Medical Journal* of Dec. 1st Dr. W. J. Pettus has recorded a remarkable case of multiple aneurysms in syphilis. A fireman, aged 41 years, was admitted to hospital on August 27th with secondary syphilis. He had had a chancre several years before which was followed by the usual secondary symptoms. He had been a hard drinker for many years. About two years before admission he noticed that his right arm was getting weaker and that there was numbness of the inner side of the hand and of the forearm. Shortly after this the left pupil became much larger than the right and the left side of the face would perspire freely while the right was dry. On admission he complained of a dull aching pain in the right arm and shoulder. There was an aneurysm of the first and second parts of the right subclavian artery projecting into the right supra-clavicular space. The apex beat of the heart was in the sixth space to the left of the nipple and was strong and expansile. A systolic murmur and an accentuated second sound were heard. The right radial pulse could scarcely be felt, the left was stronger and about 90. There was right ptosis, but the pupil was normal. The left pupil was dilated. Both pupils reacted to light. The left side of the face was almost constantly wet with perspiration. There was dulness in the hepatic region, extending down to the crest of the ilium. Severe pain was complained of in this region. It began about seven days before admission, when he became quite weak. No pulsation or murmur could be detected. He was kept in bed and 20 grains of iodide of potassium and one-twentieth of a grain of perchloride of mercury were given four times a day. The pulsation in the subclavian aneurysm gradually diminished and a steady hardening could be felt. On Sept. 25th he died from syncope. At the time of death the expansile pulsation had almost disappeared. A necropsy was made, but permission to examine the brain was not obtained. The heart weighed 11 ounces. The left side was hypertrophied and one cusp of the mitral valve was slightly thickened. The aortic valves were competent but the sinuses of Valsalva were greatly enlarged. The ascending and transverse portions of the aortic arch contained nine small sacculated aneurysms, while the entire lining showed evidence of chronic endarteritis. The innominate artery was converted into a fusiform aneurysm which involved the first and second parts of the subclavian and the right carotid arteries A great attempt had been made at coagulation, especially in the innominate portion of the aneurysm A firmly organised clot filled the sac except where there was a small channel for the blood There was a fusiform aneurysm of almost the entire abdominal aorta, beginning at and including the cœliac axis and extending down to the third lumbar vertebra just below the origin of the inferior mesenteric artery. The bodies of the last dorsal and first, second, and third lumbar vertebræ were eroded to the depth of half an inch At the origin of the cœliac axis the sac had ruptured on the right side and the blood had burrowed behind the peritoneum, forming an immense clot extending from the diaphragm to the right iliac crest, which pushed the liver forward and upward The right kidney was about twice the normal size, much flattened and pushed against the abdominal wall The medullary and cortical portions were acutely congested The left kidney was slightly enlarged and congested From the history the abdominal aneurysm appears to have ruptured about a week before admission Severe pain in the liver then developed with great weakness and nausea He constantly complained of pain over the liver and this organ could be plainly felt The temperature was very irregular, varying from 98 6° F in the morning to 102 4° at night Thus abscess of the liver was simulated Over the blood clot the peritoneum was acutely inflamed The right ptosis and left mydriasis were thought to be due to syphilitic meningitis in the region of the third nerves Possibly the brain symptoms were caused by an aneurysm of the posterior part of the circle of Willis

REG v CHILDS

AT Maidstone Assizes before Mr Justice Bruce the trial of this case was concluded on Dec. 15th, when the jury returned the following verdict "Death was accelerated by mechanical means, but the evidence was not sufficient to prove that it was caused by the prisoner" The history of the case is briefly as follows On May 12th, 1900 Katherine Flynn, age 38 years, a married woman, arrived at New Brompton from Malta Two days later she visited Mrs Childs a midwife who had attended her in three confinements On May 15th the deceased was taken ill in the afternoon and Mrs Childs visited the house and remained there from 4 30 P M until 10 P M On May 16th Mrs Childs was sent for and arrived at about 11 30 A M, and Mr E R Thomas was called in at 2 30 P M Mrs Flynn died ten and a half hours later Mr Thomas having no reason to suspect malpractice gave a certificate that death was due to syncope from peritonitis following a miscarriage From information given to the police the Director of Public Prosecutions instituted proceedings and an order was obtained from the Home Secretary for the exhumation of the body A post mortem examination was made at Strood Cemetery on June 19th, when it was found (1) that the deceased had been from four to four and a half months pregnant, (2) that abortion had occurred within a few days of death, (3) that severe hæmorrhage had taken place into the peritoneal cavity through a perforation in the upper part of the uterus of the size of a finger, and (4) that peritonitis of about 24 hours' standing had supervened The coroner's jury found 'that deceased had died from peritonitis resulting from rupture *of the uterus* [the italics are ours] but how or by what means there is not sufficient evidence to show The jury are also of opinion that such rupture was the result of illegal operation' The prisoner was committed for trial by the Chatham stipendiary magistrate on the charge of manslaughter It may be mentioned that when Mr Thomas was called in the deceased was too ill to allow a complete examination The prosecution alleged that Mrs Childs had caused the perforation of the uterus after the abortion had commenced by culpable and criminal negligence during some manipulation or instrumental interference Although it was impossible to say with absolute certainty that the perforation was not due to natural causes it was contended that it was more likely to have been caused mechanically (1) on account of the situation of the perforation; (2) the period to which pregnancy had advanced, and (3) because there was no evidence of any disease in the wall of the uterus contiguous to the rupture Testimony of a non medical nature was adduced in corroboration The sister of the deceased admitted in cross examination that the latter had had two operations performed on the uterus for "polypi" but that a child was born after each operation Counsel for the defence urged that the rupture resulted either from disease or from local weakening of the uterine wall as a consequence of the above-mentioned operations, and further, that if the rupture was of mechanical origin there was no proof that the prisoner was answerable for it The latter proposition was endorsed by the jury By way of comment we would point out that it is, to say the least, indiscreet for a midwife to take upon herself the responsibility of attending a case of abortion until it is too late for skilled medical aid to be of service The prognosis subsequently to the perforation was necessarily extremely grave and nothing short of an early operation to close the aperture and render the parts aseptic would have given the least chance of recovery We have frequently expressed the opinion that medical men are not called upon to act as police Mr Thomas was placed in a very difficult and unenviable position There was no evidence, in his opinion, to warrant him in refusing a death certificate and to this we subscribe

A TELEGRAM from the officer administering the Government of Mauritius was received at the Colonial Office on Dec 21st, stating that during the week ending Dec 20th 56 fresh cases of bubonic plague had occurred, 27 of which were fatal The total number of deaths from plague during the week amounted to 32

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION AND THE BEER-POISONING EPIDEMIC

A MEETING of the committee of this association was held at the offices, Brazenose street, Manchester, on Wednesday, Dec 19th, Professor J DIXON MANN being in the chair The principal item of business on the agenda was a report on the beer poisoning epidemic by Mr WILLIAM THOMSON, F R S Edin, F I C, of which the following is a copy —

"At the last meeting of the committee held on Nov 21st I pointed out to you that I had visited the Manchester Infirmary on the Saturday previous and had been informed of an epidemic which was peculiar to beer drinkers, and that this epidemic had been going on for three or four months Dr Sturrock, the house surgeon, stated that ptomaine poisoning was suspected I remarked that judging from the symptoms it was due to metallic poisoning and that I believed ptomaines could not be produced during the fermentation process I told him that I would undertake to investigate the matter at once I sent a messenger on the Monday following to obtain samples of beer from a house the address of which he gave me and from which he informed me that one patient who was much affected by the malady had obtained the suspected beer and requested one of my assistants to examine it for metallic poison My messenger could not find the place and this caused a delay in my examination due to my absence from town In the meantime I pointed out to your committee before anything had been published respecting arsenic poisoning, that I believed this epidemic was due to metallic poisoning and indicated the probability of lead and you requested me to investigate the matter and to report to the committee. In the meantime Dr. Reynolds discovered and published the fact that arsenic was the cause of the epidemic.

I have examined about 240 samples of beer within the last few weeks and found them to contain: two half a grain, one about one-third of a grain, five about one-fifth of a grain, three about one-seventh of a grain, two about one-tenth of a grain, and five from about one-tenth to about one-twentieth of a grain of arsenic trioxide per gallon. 174 contained amounts varying from one-twentieth part to one-two-hundredth part of a grain of arsenic trioxde per gallon and 48 samples were free from arsenic. In samples of beer brewed from the same quantities of sugar and malt, one containing, however, a greater quantity of hops than the other, the former contained considerably less arsenic than the latter. The hops, therefore, appear to precipitate some of the arsenic from the beer. I then found arsenic in beer to the extent of one-thirtieth of a grain per gallon, which was said to be brewed from malt and hops alone and I then obtained and analysed samples of malt.

I have found that a number of samples of malt contained quantities of arsenic which if dissolved in the beer in the proportion of two and a half pounds of malt to the gallon (assuming all the arsenic in the malt to go into the beer) that the contamination so produced would be as great, if not greater, than that of the average arsenic contaminated glucose beer. It is difficult to see how under the present usual methods of malt manufacture arsenic contamination can be avoided, as it is suggested by some that the fumes arising from the burning of anthracite or coke on being allowed to impinge upon barley after it has sprouted during the drying operation gives rise to a peculiarity of taste in the beer which is demanded by beer-drinkers.

In 17 samples of malt which I have examined five were free from any trace of arsenic, one contained a one-seventeenth, one a thirty-third part of a grain per pound, three contained one-fortieth, two one-fiftieth, one one-sixtieth, three one-seventieth, and one one-hundred-and-fortieth of a grain per pound. I have examined five samples of barley which were all free from any trace of arsenic except one, which was a dried barley, and this contained not more than one-five-hundredth of a grain per pound. This arsenic is contained in the vapours from pyrites in the burning anthracite or coke, as is shown by the fact that malt culms, which are the separated sprouted portion of the barley and which I understand are only used for cattle food, contain arsenic (in one sample which I examined) to the extent of one-seventh of a grain per pound. This material exists in very small grains and the fumes from the anthracite or coke would therefore affect a much larger proportionate surface than would be given with ordinary malt, which is a much larger grain.

If we take it, then, that all the arsenic contained in the malt would go into the beer manufactured and assume that two and a half pounds of malt be used for every gallon of beer, and if we take the average of a fiftieth of a grain of arsenic per pound of malt, it is evident that the beer might contain one-twentieth of a grain of arsenic per gallon—i.e., about a gallon and a quart of beer would contain a maximum medicinal dose of arsenic.

I have also found small quantities of arsenic in the hops to the extent of one one-hundredth of a grain per pound, but from the quantity of hops used in making beer the amount in the finished beverage must be extremely minute.

I have also detected arsenic in other mineral substances sometimes added to beer, but these are used in such small quantities that they could not materially affect the beer. Phosphate of soda, for instance, contained about three grains per pound; metabisulphite of potash contained a one-sixty-sixth of a grain per pound. The yeast appears to secrete arsenic from the wort, as I found it to be present in certain samples to a greater extent than in the beer brewed with it.

From this estimation of arsenic in the samples of malt I presumed that that metal must exist in considerable quantity in ordinary soot. I therefore obtained a few days ago some soot from an ordinary kitchen chimney which I have analysed and find it to contain one and a half grains of arsenic trioxide per pound. I have also examined two samples of coke and one of Welsh anthracite used in drying the malt and have found the former to contain in one sample one-twentieth, the other one-seventeenth, of a grain of arsenic trioxide per pound, whilst the sample of Welsh anthracite contained not more than one four-hundredth of a grain of arsenic rioxide per pound. Presumably, therefore, if the present process of malt drying is to be continued, anthracite an not coke should be employed by the maltster.

It is questionable how much arsenic, if any, should be allowed in any article of food. The Scandinavian Government will not allow a carpet or piece of cloth to be brought into their country which contains one-hundredth of a grain per pound, whilst some medical men are inclined to pass a beer containing a one-hundredth of a grain per gallon. This involves a problem which demands serious consideration."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

At the annual general meeting of the constituents of this Fund held at the Mansion House on Dec. 20th Archdeacon Sinclair presided in the absence of the Lord Mayor, and the following report, proposed by the Rev. Prebendary Ridgeway, seconded by the Earl of Stamford, and supported by Canon McCormick, was unanimously adopted.

The twenty-eighth year of collecting this Fund has resulted, under the Presidency of the Right Honourable Sir Alfred J. Newton, Bart., Lord Mayor, treasurer, in a total of £51,993 14*s.* 6*d.*

The constituents in annual general meeting, assembled in the Mansion House on Dec. 13th, 1899, elected the council for 1900. At the same meeting Hospital Sunday for 1900 was fixed for June 24th, and the usual invitations to coöperate were ordered to be sent to the heads of all congregations within the metropolitan area. Collections were made accordingly and have resulted in a total of £35,856 8*s.* 11*d.*

The Rev. Prebendary C. J. Ridgeway, M.A., of Christ Church, Lancaster Gate, heads the list of contributors with £1519; the Rev. Canon Fleming, B.D., of St. Michael's, Chester-square, collected £1158; and the Rev. Prebendary Eardley Wilmot, M.A., of St. Jude's, South Kensington, £655.

There is a decrease this year of £2313 from congregational collections, owing no doubt to the very large contributions collected to meet the wants of our soldiers and sailors engaged in the war in South Africa. Seven more congregations have collected this year.

In addition to the collections from the contributing congregations Mr. George Herring sent a further munificent donation of £10,000 and expressed his high approval of the manner in which the Fund was administered. Mr. Herring also offered to give an additional £10,000 if the collections could be raised to £90,000. £1090 was received from the estate of the late Mr. Thomas King, of Tisbury, Wilts. £1000 was received from "F. H." Sir Savile Crossley, Bart., again generously contributed £500 (tenth donation); "A. G. P.," £300; and "Delta" sent his twenty-second donation of £200.

The first meeting of the newly-elected council was held on Jan. 19th, 1900, when the General Purposes Committee, the Committee of Distribution, and the Special Committee for the issue of Surgical-Appliance Orders and Hospital Letters were appointed. Sir Edmund Hay Currie and Mr. Richard B. Martin, M.P., as honorary secretaries, and Mr. Henry N. Custance, as secretary, were re-elected. Dr. W. S. Church, President of the Royal College of Physicians of London, was elected to a vacancy on the council caused by the death of Sir James Paget, Bart., F.R.C.S. Eng.

The council gave its general assent to a memorial intended to be presented to the President of the Local Government Board with a view of gaining the exemption of hospitals from local rates.

On the motion of Sir Edmund Hay Currie, seconded by Mr. Sandeman, and supported by the Chief Rabbi the laws of the constitution, which have been in force during the past year, were re-affirmed.

The Rev. A. A. Drew proposed:—

> That the council for the year 1900 be re-elected (with the thanks of this meeting for their labours in the past year), for the year 1901, with the Rev. Ravenscroft Stewart, M.A., the Rev. R. Fotheringham, M.A., the Rev. E. H. Pearce, M.A., and Roger de Q. Quincey, Esq., to fill vacancies.

The Rev. Sir B. Savory seconded the proposal, which was carried.

June 16th was fixed for Hospital Sunday for 1901, and a vote of thanks to the Chairman and to the Lord Mayor terminated the proceedings.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: J. H Fergusson to the *Ramillies* and R. B. Ainsworth to the *Hannibal*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant A. D. Jameson has been instructed to proceed to Woolwich on Jan. 1st, 1901, for duty.

VOLUNTEER CORPS.

Artillery: 4th Lancashire: Surgeon-Captain J. C. M. Given resigns his commission. *Rifle:* The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment): Andrew Hutton Watt to be Surgeon-Lieutenant. 8th (Scottish) Volunteer Battalion the King's (Liverpool Regiment): William Saville Henderson to be Surgeon-Lieutenant. 1st Volunteer Battalion the East Lancashire Regiment: Arthur Foster to be Surgeon-Lieutenant. 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Claud William Marshall to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

Aberdeen Company: Arthur Hugh Lister to be Surgeon-Lieutenant (supernumerary).

TRANSVAAL WAR NOTES.

Lieutenant-Colonel R. T. Beamish, R.A.M C., is returning home invalided on board the s s. *Wakool*. Colonel A. H. Anthonisz, R A.M.C., and Civil Surgeons E. A. Chartres, T. Kay, G B Buchanan, A. C. Bird, and F. O. Stocher are returning home in the same vessel. At the request of the military authorities the Imperial Yeomanry Hospitals Committee have consented to prolong the duration in South Africa of all the Imperial Yeomanry hospitals until April.

ARMY MEDICAL SERVICE REGULATIONS.

The *Army and Navy Gazette* of last week states that the latest (1900) regulations for the Army Medical Services have been published, and many useful additions appear in them. One alteration particularly demands attention—viz., that now it is ruled that the principal medical officer of a force in the field (Part II. War, para. 626) will be attached to the staff of the general officer commanding-in-chief. This effectually deals with the stupid arrangement which relegated the P.M.O. to the base, at whose suggestion it is difficult to know. Experience in South Africa has doubtless made it clear that a restoration of the principal medical officer to his proper position was urgently needed. The new regulations, together with the "Manual for the Royal Army Medical Corps," and the "Standing Orders" for the same (1899 edition) show work well done at the medical division of the War Office during a time of great pressure.

THE LATE OUTBREAK OF FEVER IN THE PUNJAB.

There has, according to the *Pioneer Mail*, been a severe outbreak of fever of a malarial character in the Punjab during the autumn of this year. It is, however, subsiding. At Lahore and Mian-Mir European officers, civil and military, have been sufferers, while at Ferozepore the whole garrison (with the exception of British troops from the hills) have practically been placed *hors de combat*. Orders have been issued for the 47th Battery R.F.A. to be transferred temporarily to another station for change of air, but at present the men are too feeble to be moved. The disease is of the Peshawar fever type and it has prevailed in the native city as well as in the cantonments. Delhi also has been among the towns that have suffered and the mortality in some of the districts is stated to have been heavy.

RECRUITING.

In 1899 the Inspector-General of Recruiting was able to point to a return of 42,700 men who had accepted service in the regular army, as compared with 38,418 in 1898, 33,722 in 1897, and 27,809 in 1896. The increase during the present year will probably be still greater. Major-General Borrett in his report on last year's recruiting states: "The war in South Africa largely contributed to the material improvement which set in during the early months of the year; thus the year has closed as the best since the introduction of the short service system. Not only did more recruits present themselves for enlistment, but they were of decidedly better physique. While recruiting was in an unsatisfactory condition the percentage of recruits taken under standard had been very high, but in the last quarter of the year it fell materially."

THE EXPERIMENTAL TRIAL OF A NEW SYSTEM OF COOKING IN INDIA.

It will be remembered that it had been determined, as an experimental measure, to replace the native cooks employed in connexion with British regiments serving in India by cooks drawn from the regiments themselves. The new system has not proved altogether satisfactory so far as the experiment has been tried at present, but it is too early yet to pronounce any definite opinion in regard to it. The native servants of India are excellent cooks, as a rule, and it is surprising how well they contrive to succeed in their art, often under very adverse conditions, but it is open to doubt whether they are as careful in the matter of cleanliness and sanitary precautions as are Europeans; hence it was, we believe, that it was determined to give a trial to the latter.

Correspondence.

"Audi alteram partem."

"ISOLATION HOSPITALS."

To the Editors of THE LANCET.

SIRS,—As I before pointed out[1] isolation hospitals are preventive institutions or nothing. Keeping this fact in view the chart which Dr. A. J. Tonkin furnishes in your issue of Dec. 22nd (p. 1835) only adds force to my argument that these preventive institutions do not prevent. The story would have been told with added emphasis had Dr. Tonkin continued the upward curve for 1899 (Nottingham) to 2580 instead of leaving it at 1500. Your correspondent does not attempt to deny the importance of the figures, but he seeks to explain them on the hypothesis of "well-known and recognised periodic waves." I do not wish to imitate the tone of Dr. Tonkin's letter, but I may be allowed to say that such "periodic waves" are neither well known nor recognised. It is a small matter that I have failed to discover such a law, but I find on page 124 (vol. ii.) of Allbutt's "System of Medicine" these words, "On carefully surveying the records of scarlet fever epidemics in the past, it is manifest that nothing approaching periodicity has characterised its epidemic prevalence." But if it be granted that such epidemic prevalence is merely an operation of a fixed law then our efforts at prevention are absurd and unscientific. Your correspondent's line of argument only proves what was known before—that the real *raison d'être* of isolation hospitals is being lost sight of, the futility of efforts directed to prevention having been silently recognised long ago. Let your readers, Sirs, again examine Dr. Tonkin's chart by the light of the fact that he is not authoritatively supported in his views about periodic prevalence and they must conclude, with me, that that gentleman has rendered me considerable assistance. In his conduct of the defence he has made the not altogether unknown mistake of calling one of the most powerful witnesses for the prosecution.

I am accused of having dealt only with a period "when scarlet fever was epidemic in all the large towns." In view of the impossibility of reproducing all the statistics which bear on this question in one letter I did what seemed to me quite fair: I gave the returns of several of the largest towns, taking them in the order of their importance. The editorial comments which called forth my reply had reference to a booklet dealing with the 32 large towns of England and Wales, from the dates when each of these came under some form of notification to the present time. When that letter was written it never dawned upon me that any man who had in view the objects aimed at by the establishment of isolation hospitals would build up an argument founded on the admission that no effort can stay the oncoming of the periodic wave. It is a kind of logic which I find extremely puzzling. That it is giving the whole case away in the plainest manner goes without saying.

---

[1] THE LANCET, Dec. 15th, 1900, p. 1759

But to the question: What is the explanation of the tremendous fact that, in spite of the giant strides which municipalities have been making in the direction of improved sanitary conditions; in spite of the lavish spending—not to say squandering—of public money on everything which holds out the least hope of sanitary betterment; in spite of the great army of sanitary officials which is exerting itself to the utmost to improve the public health, an authority is able to tell us to-day that scarlet fever is endemic in every large town in the United Kingdom. It will be granted that the contagious element of scarlet fever—the materies morbi—is always derived from a previous case. If, then, isolation be the remedy the aggregation of 93 per cent. (practically all) of notified cases must succeed in stamping out the disease at no distant date. If this end is not attained why is it not attained? Is it not a reasonable presumption that the explanation will be found in the continued infectivity of hospital discharged patients? But we are told that the number of persons who receive their infection through the medium of the hospital is so small that it may be regarded as a *quantité négligeable*. This notion is so preposterous that one cannot help a feeling of astonishment that medical scientists have allowed themselves to be blinded by a definition so stupid and mischievous as the accepted definition of a "return" case. Dr. Tonkin, who errs in good company, informs us that "the dangerous cases are from 2 to 5 per cent." A case, therefore, which slays at large is not a dangerous case because it does not conform with the postulate laid down that a "return" case must arise in the home. As a matter of fact, the definition, trammelled as it is by limits of place and time, does not give a scintillation of the extent of injury inflicted by these institutions. A discharged patient may sow the disease broadcast and for various and obvious reasons leave the home untouched. It frequently happens that the other inmates of the home have had a mild, though temporarily protective, attack immediately precedent to the removal of the only well-marked case to the hospital. There may be no other children in the home, or, if there are, these may have been protected (in so far as one attack does prevent the occurrence of another) by previous attacks, or may be naturally immune.

Dr. Tonkin thinks that the continued infectivity of the home (after removal) may account for some of the cases which pass for return cases. If this be the case he has advanced a second argument against removal; but new centres of infection are being constantly established by discharged patients who go elsewhere than to their own homes. Cases in point: 1. The relative of a distinguished professional man resident here went straight from the hospital to her home in a distant county, where she promptly spread the disease. 2. A little girl called on her way home from the hospital at the house of a relative, where she played for 20 minutes with her cousin. In a few days the cousin sickened and was presently dead from scarlet fever. 3. A well-known tradesman was asked by a Derby friend to receive the son of the latter into his home for a few weeks' change, the son being a recently discharged patient from the Derby Isolation Hospital. The only child of the host sickened a few days after the advent of the guest and died at the end of a fortnight. Not one of these cases, be it understood, fulfilled the conditions of a "return" case. They burden no annual reports and find no place in tabulated returns anywhere. They go, however, to swell the lists of notified cases and we find them again in the Registrar General's returns. Your correspondent says that these questions will have to be discussed and determined in the near future, and in that event graciously credits me with having accomplished some little good. I am obliged to him. When the investigation takes place it will be found that other questions which have not been raised by this discussion will assume great importance. Amongst these the high mortality rate of hospital-created cases and the occurrence and mortality rate of cases of secondary infection will have to come under discussion. We shall also want to know a little more about that formidable disease, post-scarlatinal diphtheria, the incidence of which is dependent on life in hospitals and the mortality of which is 58·3 per cent. as against the 30·4 per cent. of cases of ordinary diphtheria. The discussion of questions of such serious import to us as a nation will have to be approached in a spirit somewhat different from that which some sanitarians contrive to infuse into discussions of the kind and it will have to be carried on unhampered by senseless formulæ and unlimited by meaningless definitions.

I am, Sirs, yours faithfully,

Nottingham, Dec. 22nd, 1900. EDWARD DEAN MARRIOTT.

IS THERE A PSEUDO-DIPHTHERIA BACILLUS?

To the Editors of THE LANCET.

SIRS,—The report of Dr. J. Priestley, summarised in THE LANCET of Dec. 22nd (p. 1821), deals with a question of very great importance—namely, the possibility of distinguishing between the organisms of diphtheria and pseudo-diphtheria for the purposes of clinical diagnosis. The question briefly amounts to this: Is it possible, in the time allowable for useful clinical diagnosis, to distinguish between these two with any degree of certainty justifying a negative report as to the existence of diphtheria? The question has been constantly before me during the last 12 months in which I have examined cultures from some 1800 throats made in connexion with the securing of the Greenwich Royal Hospital School against an outbreak of diphtheria. In only two or three of this number have I been able to identify anything as morphologically identical with Hoffmann's bacillus, and I certainly do not believe it to be wise or right to act upon such a presumption to the extent of treating such cases as non-infectious. Indeed, no one appears to take such a line, which is as much as to say that those who identify the organism in question, myself among the number, have not the courage of their convictions and dare not take the responsibility of acting upon their opinions. Moreover, it appears to be generally admitted that the one organism may be converted into the other. Surely this is to give up the whole position and to introduce a heresy which may attain very dangerous proportions. In order to preserve a distinction between two organisms, it must be shown that they are at all times and under all circumstances incapable of transmutation. If ever one can turn into the other, then the only logical deduction is that they are essentially identical.

Dr. R. T. Hewlett, who has studied this subject exhaustively, after giving a careful tabular statement of the differences between the two organisms, makes the damaging admission just referred to, the apparent possibility of conversion, and no conclusive one of the tests which he furnishes is capable of application within the time at the disposal of a clinical investigator. This being so, it seems plain that it is the duty of every person who bears responsibility in this respect to refrain, when an organism morphologically resembling the diphtheria bacillus is found in a culture, from stating that the organism so found is not a dangerous one.

The whole matter is, as I have said, summed up in the one statement which I desire to emphasise in every possible way—namely, that *if there be a possibility of converting the pseudo-diphtheria bacillus into the diphtheria bacillus, then there is no such thing as a pseudo-diphtheria bacillus at all*, and this is, I confess, my own present position.

I am, Sirs, yours faithfully,

EDWD. C. BOUSFIELD,

Dec. 22nd, 1900. Bacteriologist of the Borough of Camberwell.

THE OPERATION OF CIRCUMCISION.

To the Editors of THE LANCET.

SIRS—Mr. D'Arcy Power, in his interesting paper on Some Disappointments of Surgery,[1] makes the following very apposite remarks:—"There are few operations more often performed than those of circumcision and for hare-lip, yet there are few which may give more disappointing results. The aim of a perfect circumcision is to remove just so much of the foreskin as is necessary to liberate the glans penis and to avoid removing so much as to leave the patient a '*curtus Judæus*.' Such a perfect operation is rare, but I do not recollect that the difficulties were ever pointed out to me." It is undoubtedly true that such a perfect operation is rare, but why is this the case? The fact is that circumcision is generally regarded as a very simple operation and one which any surgeon feels competent to undertake, but if one may judge from a good many cases which come under notice from time to time the object of the operator would appear to have been not to remove just so much of the foreskin as is necessary to liberate the glans penis, but to cut away as much as possible of the prepuce without injuring the glans penis, which is thus left absolutely denuded from apex to base.

---

[1] THE LANCET, Dec. 22nd, 1900, p. 1789.

It may be presumptuous in me to suggest that possibly the text-books on surgery are partly to blame for the extensive mutilations which are frequently practised under the name of circumcision, but the usual method described in most books of placing the circumcision forceps over the line of the corona and then allowing the glans to slip out of the way when the whole of the skin beyond the forceps is cut off has always seemed to me to err in the direction of doing too much. The plan I have generally adopted and found successful is to first seize and gently draw out the end of the prepuce with a pair of artery forceps and then to apply the circumcision forceps not over the corona, but over the end of the glans penis which it just clears. With the subsequent retraction which immediately ensues and after the mucous membrane is slit up along the dorsum it will be found that quite sufficient skin has been removed, no unnecessary mutilation has been produced, and the object of the operation has been satisfactorily attained.

All this may seem a small matter, but no detail, however small, is unworthy of attention in even the most trifling operations of surgery.—I am, Sirs, yours faithfully,

E. DYKES BOWER, F.R.C.S. Edin.

Gloucester, Dec. 24th, 1900.

CACODYLATE OF SODIUM: A WARNING.

To the Editors of THE LANCET.

SIRS,—It is unfortunate that the lay press should have selected for recommendation as a popular remedy so lethal an agent as cacodylate of sodium. We are told that although it contains 55 per cent. of arsenious acid it has none of the toxic action of that drug and that it may be given by mouth in doses of from 20 to 40 centigrammes with perfect safety. This is not my experience. On Dec. 9th I ordered for a patient, aged 21 years, suffering from phthisis, one grain of cacodylate of sodium in a pill. On the following day there was a distinct odour of garlic in the breath and on the second day this was much more marked, was noticeable at some distance from the bed, and suggested the smell of phosphorus. On the third day the patient vomited twice and the odour of the breath was almost gangrenous in character. On the next day, after 11 doses had been taken, the patient was found to be suffering from many of the symptoms of arsenical poisoning. Her face was pallid, the eyelids were œdematous, the conjunctivæ were injected, the tongue presented the appearance of a piece of raw beef, and there was complete loss of appetite. In addition there was arsenical neuritis. The patient complained of pains in the limbs, especially in the lower extremities. There was tenderness on deep pressure over the course of the nerves, more marked in the left leg than in the right. She was unable to move the left leg and there was marked loss of power in the extensors of the left wrist. The patellar reflexes were not abolished, but the attempt to elicit them caused great pain. There was no diarrhœa and there was no albumin in the urine. The odour of the breath disappeared within 24 hours of the suspension of the remedy, and her general condition improved, but the loss of power in the leg and in the arm still persists. The drug was obtained from one of the most reliable chemists in London and was made by Messrs. Pointet and Co. of Paris. It was given in about one-third the minimum dose recommended by Gaillard and other French physicians and its effects were carefully watched, but in spite of all precautions these untoward effects ensued. Gautier states that it may be given hypodermically, in doses of three-quarters of a grain. My experience may be exceptional, but I cannot but think that it is a dangerous remedy which should be employed with considerable caution. I am, Sirs, yours faithfully,

WILLIAM MURRELL.

Welbeck-street, W., Dec. 16th, 1900.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The Carmichael prize of £120 has been awarded by the President, Vice-President, and council to Mr. Horatio Nelson Hardy.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Sanitary Improvements under the Epidemic Diseases Act.—Municipal Subscriptions to the Pasteur Institute of India.—The Health of the Cities of Bombay and Calcutta.—The Plague.

THE Epidemic Diseases Act has been made use of for other purposes than plague administration, and not the least of them has been the improvement and demolition of insanitary buildings. This Act gives powers not possessed by municipal authorities and has been taken advantage of in Bombay city, where during the past year 271 houses and sheds have been demolished and 629 declared unfit for human habitation. In addition compulsory improvements have been effected in a very large number. It is to be hoped that the powers thus given during a plague epidemic will be transferred to municipal authorities as a permanent measure. Few if any improvements have been carried out under these powers in Calcutta.

The authorities of the Pasteur Institute of India have been inviting certain municipal and district boards to contribute annual subscriptions in aid of the Institute. At Lucknow, notwithstanding some opposition, it was carried that "as the Pasteur Institute is a scientific institution for the alleviation of the sufferings of humanity it should be aided by the board and that inquiries be made as to the financial condition of the institution with a view to the board's making a suitable grant." On the other hand, at Calcutta, where the application was rejected, it received opposition from the chairman of the municipal board and another European member.

The draft report of the municipal commissioner for the city of Bombay for 1899–1900 has lately been presented. In it he refers to the exceptional rainfall of only 35·9 inches, which was less than half the normal and half of which even occurred in the month of June, and he mentions how the water-supply became not only scanty but impure. At the same time the worst famine of the century commenced, causing local destitution in Bombay city and a large immigration of destitutes from the famine-stricken areas. The mortality of the city has been very high, there having been 4473 more deaths than in 1898 and the death-rate has been 68·67 per 1000 per annum. The total deaths for the year were 56,434, being 17,785 above the average. In the month of March when plague was at its worst 10,183 deaths were recorded. Plague is credited with 15,796 victims, and diseases of the respiratory system caused 8650 deaths, phthisis 6029 deaths, fevers 5063 deaths, and diarrhœa and dysentery 4286 deaths.

In consequence of the high infantile and maternal mortality in Bombay city the municipality has appointed a committee "to consider and report on the desirability of entertaining one or more diplomaed native midwives for each ward of the city for giving relief to poor women in need of assistance at childbirth." At present the women doing this work are ignorant and dirty and they spread disease far and wide.

The general mortality in Bombay city shows no signs of diminution. For the week ending Dec. 4th it was 804, as against 790 during the previous seven days. During the past quarter it has been at the rate of 84·09 per 1000 per annum. Amongst high-caste Hindus the rate is 79·72 per 1000, amongst Mahomedans 83·55, amongst Parsees 38·51, and amongst Europeans 39·32.

The general mortality in Calcutta is also high and shows no sign of diminution. For the week ending Dec. 1st there were 691 deaths, against an average of 552, a rate of 52·1 per 1000, against an average of 42·2. In both cities plague seems again on the increase. 70 deaths are recorded this week in Bombay and 76 in Calcutta.

Plague has again broken out in the Punjab and at Bangalore it has much increased. The members of the dhobie (washerman) class are the chief sufferers there.
